For example, any even partial elimination of space charge would have caused the current to rise to the saturation value far below 250 volts and if that had occurred the tube could not have been used as an amplifier. For example, in the old DeForest audion the tube could ordinarily not be used as an amplifier or detector at voltages over 30 and sometimes at 25 volts or 40 volts the current would become limited by saturation because space charge would not be effective and the current would rise to the saturation value. The potential on the grid or plate would then not be able to control the current and its usefulness as an amplifier or detector would disappear.

Q. 150. Let us go back to your notebook No. 458, Plaintiff's Exhibit 131, and will you refer to page 48 of this notebook and tell us what is referred to therein and your recollection as to it.

A. On page 48, under date of April 7, 1913, I refer to White having tried out the D.C. transformer and I show the diagram with the audion connected to 250-volt shop line and a spark gap arranged across the terminal of the inductance. Then on the next page I describe the other circuit which White and I tried out, in which there is slightly different connection. I do not need to describe it in detail but say that White further tried out the following connection. I have just shown from White's notebook that it was audion No. 2 that was used in these two tests.

Q. 151-54. Will you refer to page 79 of the same notebook and I think you will find some reference to Wien. Please tell us who was Wien?

A. Professor Wilhelm Wien was a very well known Physicist who had received the Nobel Prize in 1911 for his work on Radiation of Light. He gave a series of lectures in Columbia University in the spring of 1913, and Dr. Dushman and I attended some of these lectures. I fix the date of this entry on page 79 under April 30, 1913:

> "On Monday went down to New York to the last of Wien's lectures. On the way back had talk with Dushman as result of which I saw Whitney yesterday and came to following decision, etc.: Dushman will work with White and me on D.C. transformer. Work to be arranged thus:
>
> "White will develop audions for wireless and relay for low voltages and low currents.
>
> "Dushman will take up work with the new Gaede pump and work on high voltage, hot cathode rectifier and relay."

And then further details are given as to the work that had been lined out for Dr. Dushman. I remember particularly the reason or the thing that made me get interested in having Dushman start work at this time, and that was in connection with these lectures of Professor Wien. After this lecture, we invited Professor Wien to the Manhattan Hotel in New York City. Dr. Dushman and I did, and we spent the evening with him and found him a most delightful man and had long conversations on scientific work, and the thing that impressed me particularly, after I had described the work that we had been doing in the laboratory to him, with pure electron current, . . .

[At this point the witness began to testify to a statement made by Prof. Wein, and thereupon counsel for defendant objected, and after argument, the question of admissibility of the testimony was laid over for further argument and consideration.]

By Mr. Lunt:

Q. 155. Now, will you refer to page 101 of this same notebook, No. 458, Exhibit 131, and explain the significance of the statement that you find there?

A. On page 101?

Q. 156. Page 101?

Mr. Haight: May we have a copy of that?

A. On page 101, under the date May 12, 1913, is the entry:

> "Today White and I tested out one of his new audions with high frequency currents (about 75,000 cycles).
>
> "The results were exactly as I had expected and help to prove the correctness of my theories as to the action of these relays."

And then there follows a diagram of the connections which were used for amplifying these radio frequency currents. Now, the object of this work was to try out Alexanderson's scheme of radio frequency amplification. The notebook on the preceding page refers to Alexanderson and Day having come over and I showed them several of the audions that we had made up.

After the diagram, there is a table which defines the different parts of the diagram, and the B battery, that is the plate battery, as marked by the symbol J, and on the next page, 102, it is stated that this battery J is a storage battery of 120 volts. These tests were not made in our laboratory. They were made in Alexderson's laboratory, which was in another place. I remember that very distinctly, using the Alexanderson alternator two kilowatt—100,000—cycle alternator as a source of power and amplifying the currents and reading them on a sensitive millivolt meter used as an ammeter.

On page 112 under the same date, May 12th, I give in more detail the diagram of the connections which were to be used for the test of the geometrical tuning circuits of Alexanderson. That circuit is described there.

Then on page 130, under the date of May 18th, is a summary of the work that we have just completed on Alexanderson's tuning in geometrical progression, and I stated there that it was demonstrated that the thing worked as predicted and lower down on the page it is stated:

"A hot cathode relay like that we have made responds perfectly to frequencies as high as 105,000 cycles. No sluggishness noticeable," and so forth. And then a statement that it would be good until ten million cycles.

Q. 157. What did you mean by the statement like that you had made?

A. The type of audions we had been using with White, that White had been making up like the audion No. 2. That was the type of audion used in these tests.

On page 131, continuing is a description of a further application of these tubes that is planned at that time. It is stated:

> "We can obtain A. C. of high frequency from a D. C. source of power by such a relay. Thus the batteries J supply the power for the A. C. current."

And then below a couple of sentences that are not pertinent and then:

> "It simply remains now to carry this out on a larger scale with higher voltages and higher currents and thus to obtain higher efficiencies. Dushman will carry on this work. Of course by a rectifier we can obtain D. C. from the A. C. circuit."

On page 132 it is stated:

> "Tuning by geometrical progression according to Alexanderson's scheme is an accomplished fact."

Q. 158. What did you mean by that?

A. We had just completed our tests with Alexanderson in which we had to study the selectivity of the system showing that by means of radio frequency amplification with the circuits in ~~each audion~~ tuned for the radio frequency we were able to obtain a selectivity for a given signal much higher than we had ever been able to obtain by any other circuits and together with the advantage that the system had a certain breadth of band in which it was sensitive. There was a certain range of frequencies for which the device had an unusually high sensitiveness and on both sides of that it was remarkably insensitive.

It is just those advantages that we found at that time and demonstrated that have made the radio frequency amplification so very important today in the radio field. This was done with audions of the character of audion No. 2 and I think would only have been possible with such audions. I do not think we could have made any of those tests, at least I thought so at the time, that I could not have been able to make any such tests without the character of audions that we were then using.

Q. 159. Was Dr. Alexanderson present at this demonstration of the geometrical tuning?

A. I do not think he was present at the last part of it. Those tests extended over several days and I think he was present at the first part before we completed them. I think he was present while we were showing that the audion could respond and could amplify radio frequency currents but at that time we did not have the whole set completed.

Q. 160. How long did this general demonstration take, or rather, over what period of time did it extend?

A. I think it was from about May 9th to May 18th.

Q. 161. Now, will you refer to page 138 of your notebook, Exhibit 131, and explain the significance of the entry on that page.

A. This describes a circuit in which a resistance is used in the plate circuit to couple one audion with the next following one. That is to couple the plate circuit of one audion with the grid circuit of the other one, a resistance coupling was used. Several other times before, such circuits had been used, but this is the most practical form of circuit and it was this work which led to our filing an application on that form of coupling. It involved the use of this same audion.

Q. 162. Can you give us the date of that entry or when the work was done?

A. The date was May 18, 1913.

Q. 163. I hand you a copy of your patent, No. 1,297,188. Is this the patent referred to?

A. Yes.

Mr. Lunt: I offer it in evidence.

Mr. Haight: I do not see the materiality of it.

(Discussion.)

The Court: I do not believe that would let it in. I think the objection is well taken.

Q. 164. Will you now refer to page 156, of this notebook of yours, Exhibit 131, and state what the significance of the entry there is?

A. This simply refers to the fact that I spent part of the afternoon looking over White's curve on D. C. characteristics of twelve different audions that he has made up. The curves show that there is a linear relationship between the plate voltage and the grid voltage, that is, that the effect of the grid and plate can be replaced by a properly chosen average of the two. This is an experimental verification of the fact that I made use of this morning in deriving the 2/3 power law as applied to a three-electrode tube.

Q. 165. I think I have inadvertently passed over something that I wanted to refer to. Will you go back to page 111 and explain the significance of the entry there.

A. There is an entry on page 111, under date of May 12th, which was made at the time that we were working on radio frequency amplification where we used one of these high voltage audions to measure the radio wave lengths or radio frequencies. I say, "This afternoon the contrast between the beautiful reliability and accuracy of this form of wave measurer as compared with the ordinary wave detector was very apparent."

Q. 166. What was the date of that?

A. May 12, 1913.

Q. 167. Will you refer to pages 176 and 177 of Exhibit 131 and state briefly what are the plans for the use of audions there referred to?

A. On page 176, under date of June 17, 1913, after speaking of a new man who had come to work with White on audions, this man's name being William Rogers, I state: "At present the program is 1. Try out Alexanderson's plan of using telefone to control high frequency current and thus send telefone messages by wireless. White will try this out for short distances, etc., with ordinary audion and then we will get larger one (I will ask Dushman to make up one) that will handle say 40,000 volts and 0.5 amp. and this can then be used for actual long distance sending."

The ordinary audion that I referred to there is the improved form of audion which White had been using of the type of audion No. 2.

Mr. Haight: I suppose it is understood that Dr. Langmuir endorses on the stand all of these statements that he has been reading. I mean by that that they refresh his recollection to the extent that he can swear to the things that appear there.

The Witness: Yes.

Mr. Haight: I make that observation because it seems to me that the form of my friend's questions were based on the idea that the book was primary evidence and not the testimony of the witness.

Q. 168. Without going into detail, was the plan of White subsequently carried out?

A. Yes.

Q. 169. Will you refer to page 185 and give your recollection as to the matter there referred to?

A. On page 185, under date of June 18, 1913, I made the entry: "Dushman has made fine progress. He has the large audion in good working order. It consists of two tungsten plates and grid of 1.5 mil tungsten wire wound on one-quarter-inch rod for support and a filament about three inches long. There seems to be no difficulty in operating it at 20,000-40,000 volts and 0.1 amp."—(that is 100 milliamperes)—"(probably even at 0.5 amp.)."

I might say that that tube at that time was still connected to the pump. I remember that we had these electrodes in a bulb which was about six or seven inches in diameter with side arms which contained the leads of the terminals to the electrodes and that this was connected with a very large diameter tube connected to the Gaede molecular pump, which is a very high speed pump, pumping about fifteen or twenty times faster than any pump we had up to that time, and in order to utilize the full benefit of the speed of this pump, we had a tube which was probably an inch and a quarter in diameter running right up to the big audion. So that we could operate this audion on the pump without making any attempt at that time to seal it off.

In this way we could study the characteristics of this audion at high voltages even though gas was still coming slowly out of the electrodes. The gas was being removed by the pump as fast as it was coming out.

Our intention was to get the gas out of the tube sufficient to seal it off but before we reached that condition we would at least know something of the practical operation of the device.

We had our high voltage transformer and all the electrical circuit connected up and the Gaede molecular pump right in front of it and a gateway or screen fence around the whole thing so that no one would get hurt or injured by the high voltage current,—because it could have easily killed any one who would have touched it,—so that we had a great many safety appliances in connection with it.

Q. 170. Will you refer to page 193 and state what recollection you may have as to the matter there referred to? Please also give the date of that entry.

A. At page 192 under date of June 19th, is a summary of the different things that I planned out for Dushman to do in the way of building tubes of special construction and the use of circuits. The intention is stated to use much larger currents.

On page 193 among the list of things that are planned is the following:

> "Build hot cathode rectifiers, two of them at least, one with two plates. These to be sealed off. This will require Dushman to get familiar with methods of getting gas out of anodes and etc., such as Coolidge has used."

The sealing off of the device will be much more difficult than operating on the Gaede molecular pump. But it is what I planned to have Dushman do.

On page 222——

Q. 171. May I ask you first to refer to page 200 and state your recollection as to the matter referred to in that entry?

A. On page 200 is a diagram of a circuit showing the use of the grid leak. There was a condenser connected to the grid which was shunted by a very high resistance and the object is stated there, there is also a battery "to keep the grid slightly positively charged enough so that a measurable current flows to the plate.

"Now, when signals are received the grid tends to become negatively charged. The resistance and the condenser should be so chosen that the condenser will discharge itself in say one 1/1000 of a sec. but yet not become more than very slightly charged in say 1/200,000 sec."

The use of the grid leak was a very important element in using tubes that we were then making as detectors. In the old DeForest audion, there was enough positive ionization under normal conditions to keep the grid from becoming negatively charged, so that grid leak was not very important. There was enough natural leakage in the tube itself due to positive ionization, so that the leak was not needed; but with the much higher vacuum that we were using, and with this pure electron discharge at high voltages, there was no appreciable positive ion current flowing to the grid. Whereas, when the grid became positively charged, as it did, when it received signals, it took up electrons, but unless there was a grid leak, you could never lose these electrons again, so that it became more and more charged and it was to overcome this defect that I devised the scheme for using the grid leak.

Q. 172. Did you obtain a patent along these lines?

A. Yes.

Q. 173. I show you a copy of Patent No. 1,282,439, and ask you whether this is the patent.

THE COURT: Applied for when, and issued when?

Q. 174. Will you answer that?

A. The application was filed October 29, 1913. Yes, this is the patent. It shows the use of the grid leak in the detector——

THE COURT: Just a moment while Mr. Richmond is looking at the patent.

MR. HAIGHT: We object to the patent.

THE COURT: Your reasons?

MR. HAIGHT: On the ground it is immaterial.

(Discussion.)

MR. DAVIS: If it is established that he did make this invention of the grid leak, and filed a patent application for it on a certain date, and that the patent is granted, that is all we are interested in.

The Court: Well, then the offer of the patent itself is withdrawn?

Mr. Davis: I think that is evidential. I think those facts are evidential.

The Court; I do not know just where that line should be drawn.

Mr. Davis: But the effect of the particular language of the patent I do not think is evidential.

The Court: No.

By **Mr. Lunt**:

Q. 175. I will now ask you to explain what your recollection is as to the entry on page 222 of your notebook, Plaintiff's Exhibit No. 131, and to explain particularly the statement reading as follows:

"Dushman has sealed off the first successful hot cathode relay."

The Court: Does that involve some minutes consideration, Dr. Langmuir?

The Witness: Not very long.

The Court: Very well.

The Witness: This refers to the relay or the audion which I had previously referred to. For example, the same one that was described on page 185 of this notebook. By that time we had for convenience come to give different designations to different types of devices. It was our custom at that time to speak of the tubes that White was making as audions, and the large power tubes, which Dushman was making, as hot cathode relays, although at an earlier date such a distinction was not usually drawn. It was simply a matter of convenience in nomenclature. The emphasis in this sentence, I think, should come on the fact that it has been sealed off. The tube had been operating for quite a while before that on the pump. The tube is now sealed off successfully. That is, it was a large power tube. It stands, as I said, in the notes up to 100 milliamperes and 10,000 volts without blue glow. It took two days of cathode bombardment up to 20,000 volts to free the anodes and the grid from gas. Then I go on to say that

"Yesterday and today Dushman and I have been trying to use this relay to produce high frequency oscillations.

"This afternoon we found the very fine result that the apparatus produced high frequency oscillations better by itself than when the grid was stimulated by the small oscillator."

That is, we tried first to so amplify high frequency amplifications from another source, but it produced its own oscillations, and it was those oscillations that we have later measured the wave length of, that is, this tube was being used then as a high frequency oscillator.

(Whereupon at 5 P. M. adjournment was taken until Tuesday, November 2, 1926, at 2 P. M.)

U. S. District Court, Wilmington, Del.,
Tuesday, November 2d, 1926,
2 o'clock P. M.

FOURTEENTH DAY.

Before:

Hon. Hugh M. Morris,
U. S. District Judge.

Appearances: As before.

Mr. Davis: If your Honor please, I made a statement during the trial as to the priority of the Coolidge drawn wire filament. I want to be clear that there is no misunderstanding about that statement; that is, I have no hesitation in admitting, because I think it to be a fact, that the Coolidge drawn wire filament——

The Court: Will you wait just a moment, for Mr. Darby?

Mr. Darby: Pardon me.

Mr. Davis: I say I have no hesitation in admitting as I meant to admit, that the Coolidge drawn wire filament in its most perfect thoriated form was known to Dr. Langmuir before he made the invention of the last three patents in suit, which was, I suppose, at the time, the only thing in which the defendants were interested. Now, I do not want my statement to be construed to mean that it was on the market in that form at such a time, or at any particular time, because I think that investigation would show that the first drawn wire filaments that were put out, were made by the Battersea Crucible process, which is described in the Coolidge patent, and which was filed later, I do not know just when it was, that the thoriated filament began to be used. I say that lest there be misunderstanding as to any statement I make.

Mr. Darby: I understood from your statement that you admitted that the thoriated tungsten filament had been on the market prior to some time before the middle of 1912, which I understand to be unqestionably the fact.

Mr. Davis: If it is so, it is outside of my knowledge, and if it is important, I shall not oppose any objection to the fact being proved. I will co-operate to prove it.

Mr. Darby: That will be entirely satisfactory to me if I elicit that statement from you as a stipulation before the defendant closes its case.

The Court: If the stipulation was modified for any reason, why then, of course, you will be at liberty to establish what proof you desire. You can have such reasonable time as you desire for it.

Mr. Davis: We will get the facts, if your Honor please, and submit them to Mr. Darby, if necessary.

Irving Langmuir, resumes the stand:

Direct Examination (Continued).

By Mr. Davis:

Q. 176. Do you know Professor Wien?

A. I do.

Q. 177. In a few words, who is he?

Mr. Haight: Cannot we avoid that by putting the question directly to him of what you want to get?

Mr. Davis: It will involve the question of being somewhat leading.

Q. 178. Is it or is it not true that Professor Wien is a very distinguished physicist who has won the Nobel Prize and who has done a great deal of work and published a great deal on electrons and their properties; that you met Dr. Wien at dinner in the spring of 1913, and that you then and there disclosed to him that you and your associates at Schenectady had tubes which operated by pure electron discharge, substantially independent of positive ionization, and if your answer to that question is yes, then I will ask you whether or not Professor Wien on hearing that statement expressed astonishment or incredulity?

Mr. Haight: I would rather have had it the other way. I think the question should be what did Professor Wien then say.

Mr. Davis: I am perfectly willing to put it that way.

Mr. Haight: I object to the question on the ground that what Professor Wien may have said is irrelevant and objectionable under the hearsay rule.

Mr. Davis: Then I think I will go back to my first question of whether he did or did not express or show incredulity or astonishment and I prefer to leave it in that form.

Mr. Haight: That would call for a conclusion from the witness and we will get nowhere on that.

(Discussion.)

The Court: I am of the opinion, Mr. Davis, without an opportunity to investigate it, that it is not admissible, and that its admission would be as damaging to the field of evidence as would be the admission of hearsay evidence. I can understand if these were a party to a cause, there might be some distinction there which I do not appreciate, but if he was a party to a cause would be one thing, but to permit a person who was not a party to a cause, who believed or knew a certain thing, I think is extending the field of evidence more broadly than would be justified. Consequently, I sustain the objection, but I give you the permission, of course, to put it in under Rule 46, if you want to.

MR. DAVIS: I do not care to prolong the argument, your Honor. I will, if your Honor will permit me, take advantage of the rule and ask the witness to answer the question which is in substance yes or no to the long question.

[The witness was then permitted to give his answer under Rule 46, and it was ordered by the Court that the answer should appear in an appendix to the record.]

By MR. LUNT:

Q. 181. Will you now refer to your notebook No. 504, Plaintiff's Exhibit No. 132, and state whether this notebook as well as the other notebooks, Plaintiff's Exhibit No. 101, notebook 413, and Plaintiff's Exhibit No. 131, notebook 458, were books which you regularly kept in the course of your work and in which you kept notes of your work?

A. Yes.

Q. 182. Was it your duty to keep these books?

A. Yes.

Q. 183. And were all the statements which you made in all these notebooks true according to your belief at the time you made the respective notes?

A. Yes.

Q. 184. Will you now refer to page 186 of your notebook No. 458, Plaintiff's Exhibit No. 131, and give us your recollection of the note which you there made?

A. I find on page 186, and in the upper part of 187 of this notebook, reference to an experiment or a test which I remember very distinctly, that was made with the high voltage tube that Dushman had been operating while still connected to the pumping system. This test was essentially like that which I had made with White a few months before, where I used the audion to interrupt a plate current, which was passing through a high inductance coil, and in that way obtained sparks 0.3 millimeter long. The same experiment was now tried with the tube which Dushman had made, and negative voltages were applied to the grid, and then it was noted:

> "With about 2400 volts in the plate circuit (this taking the place of the primary D. C.) a ¾ inch spark about 15,000 volts was obtained across the terminals of the inductance in plate circuit."

That means that with this tube we were able to get grid control; that is, to be able to control the plate current with the grid, even when voltages of 15,000 volts were acting on the plate. In other words, it was acting as an audion normally operates, but with 15,000 volts——

Q. 185. I find I have omitted something as we went along——

A. I do not think that quite finishes that—yes, I think it does.

Q. 186. I find I have omitted something as I went along, and I would now like to take you back for the moment to your notebook No. 413, Exhibit No. 101, and ask you your recollection as to the matter contained on page 223 of that notebook, I think under date of February 7, 1913?

A. Yes, that is correct. On this page is the statement:

> "Alexanderson has been wanting a method of controlling high frequency discharge by means of the waves produced by a telephone. By an arrangement of tubes corresponding in principle to the audion he proposes to interrupt his oscillatory discharge by means of the 'grid' connected to telephone. This I think could be accomplished by a hot cathode tube."

And a sketch is shown of the arrangement of audions for this purpose.

Q. 187. Was it or was it not a fact that this was subsequently accomplished?

A. Yes, this was accomplished and it was the basis of our development of radio telephone transmission.

Q. 188. I would now like to call your attention again to your notebook No. 504, Plaintiff's Exhibit No. 132, and would ask you to tell us your recollection as to the matter on pages 48 to 50, giving the date of the entries?

A. May I ask that page again?

Q. 189. Pages 48 to 50?

A. Under the date of November 11, 1913, is the following entry:

> "Relay for wireless telephone. This morning Dushman and I tested out the hot cathode relay tube with 10,000 volt high frequency current from Alexanderson's machine."

This was a two-kilowatt 100,000 cycle generator.

"The results were most encouraging. By a variation of grid potential of only about 30-40 volts the load taken from the machine was made to vary from 80 watts to about 400. In other words, a load of about 300 watts was controlled by a D. C. potential of about 30 volts with a current of probably not over 0.1 milliampere. Thus an energy of about 300 W was controlled by about .003 watts or a power magnification of about 100,000 fold."

And then there is a diagram of the connections that were used.

I remember that test very distinctly, for it showed the operation of Dushman's first audion, or what we called at that time the hot cathode relay at voltages for 10,000 volts for actually controlling and modulating high frequency power of 400 watts energy, just such as would be needed in the antenna of a wireless station, which was to send out radio telephone signals of 400 watts energy. We subsequently used the tube with practically this kind of a circuit in actual wireless station, and sent messages from Pittsfield to Schenectady, between Pittsfield and Schenectady.

Q. 190. Will you refer to page 52 of this same notebook, Exhibit No. 132, and tell us your recollection as to the matter noted on that page?

A. Under the date of November 19, 1913, this refers to the matter of terminology. We needed a name for the high vacuum devices which we had made, in order to distinguish them from older devices which operated in the presence of gas, and it is noted here a large number of Greek terms are suggested, and finally it is decided:

On November 22, on page 54 of this notebook:

"Have decided to adopt the names *Kenotron* for electron discharge tube." "*Pliotron* for electron discharge relay."

Mr. Darby: Will you give me the date of that?

The Witness: November 22, 1913.

Mr. Darby: That is subsequent to the valid date? Does that make that book available?

Mr. Lunt: It is in evidence.

Mr. Darby: That particular book?

Mr. Lunt: Yes.

Q. 191. Before passing that, I would like to ask whether you ever received distant wireless signals making use of any of the apparatus which you may have already described in giving your testimony?

A. In January, 1914, we used audions of the type of—practically exactly like audion No. 2 that I have already described. I mean, the same type of construction. We used those audions to receive wireless signals, but particularly continuous wave stations. For this purpose, we used Alexanderson's system of tuning in geometrical progression, along early in 1914, probably February and March, with a relatively small antenna, and using two stages of radio frequency amplification, each stage being tuned, and a detector tube, and another tube to produce high frequency oscillations, so that we could detect the signals by the heterodyne method. We received radio signals from San Francisco and from Honolulu quite regularly. Those were sent from Honolulu at about six or seven thousand meter wave lengths. And we were frequently able to overhear the signals from Honolulu when the station at San Francisco asked to have them repeated, because they could not get them. That was a thing that impressed us very much at the time, and I think it would only have been possible by the good tubes we had at that time. We were using some 125 up to 250 volts on the plate.

Q. 192. Did you read a paper setting forth some results of your work on electron devices, and when was it?

A. Yes. I read a paper I think in October, 1913, which was subsequently published in the *Physical Review* in December of 1913.

Q. 193. Will you refer to that paper, which I think is Plaintiff's Exhibit No. 21, and call attention to the parts of the article or paper, especially those that may have to do with the preparation or building of tubes. You might read those parts if they are not too long.

Mr. Haight: I am wondering whether that is really going to help us any. The paper is in evidence. It speaks for itself.

The Court: It seems to me to be a duplication; does it seem otherwise to you?

Mr. Lunt: Well, except that it renders more intelligible the answer to subsequent questions; but of course it can be looked up and it is in the record.

The Court: All right.

Mr. Lunt: I will do just as your Honor says about that.

The Court: The record is going to be pretty long, and if there is no substantial point in duplication——

The Witness: May I refer to the page?

Q. 194. If you will indicate where those parts are, without reading them, or perhaps just read the first few words, to make it clear?

A. On pages 479 and 480 is a description of the methods of preparing electrodes and exhausting the tubes in such a way that a pure electron discharge may be obtained.

Q. 195. Is that the only place you wish to refer to or point out?

A. I think that is enough.

Q. 196. When and where was this paper, Plaintiff's Exhibit No. 21, read?

A. It was read in the Physics Lecture Room of the Physics Department of Columbia University.

Q. 197. And when?

A. October, 1913.

Q. 198. And what transpired at that meeting?

A. There was considerable discussion after the meeting, mostly by Dr. Arnold. He pointed out to me that the 3/2 power law had been previously published by Child in 1911, and that was for the case of parallel plane electrodes. In my paper I had also given the derivation for electrodes in the form of a wire as the center in the axis of a cylinder. Dr. Arnold also stated that he felt that it was very doubtful if I had really obtained currents at such voltages as I had spoken of (250 volts), that were free from blue glow and ionization effects. After the meeting I had a longer talk with Dr. Arnold and he told me that they had been working on electric discharges in evacuated tubes from hot cathodes and had used the Wehnelt cathode, and said that they were particularly interested in low voltages, much lower voltages than those I had been talking about. I think that he spoke of voltages of 20 to 30 volts as being the voltages that he intended to use in operation. The impression that I got at that time from the conversation with him was that they had not gone very far in making devices utilizing thermionic currents in vacuum.

Mr. Richmond: Your Honor, I object to the drawing of a conclusion in the statement of an impression.

The Court: The objection is sustained unless you desire to be heard, Mr. Lunt?

Mr. Lunt: Well, your Honor, so far as his answer concerns the drawing of conclusions, I have nothing to say.

The Court: Then the last sentence is stricken out.

Q. 199. What other papers have you written regarding this work, at least, so far as concerns the period up through 1915?

A. Two other papers were published on the same subject in Germany in I think January and February, 1914, which cover somewhat the same ground that was covered in this *Physical Review* paper that I have just spoken of, but they were entirely separately written papers, and I think in many ways the German paper went into a good deal more detail as to the method of obtaining high vacuum and getting a pure electron discharge. Those two papers were published in the *Phys. Zeit.* Then in April, 1915, I read a paper before the American Institute of Radio Engineers, and that paper was published in the *General Electric Review*, and also in the transactions of the Institute of Radio Engineers. That paper dealt with the applications of a pure electron discharge to radio telegraphy and telephony.

Mr. Lunt: I believe, your Honor, that these are already referred in the Interference record.

Q. 200. You have described your work on the improved audions in relays and on related matters. Will you now review the distinguishing characteristics of these devices, which, in your opinion, affect that practical operation?

A. The pure electron discharge devices that we were able to build in 1913, and beginning in the latter part of 1912; and the practical part of the devices that we built in 1913 distinguished themselves over the older devices, such as the DeForest audion and Fleming valve, in a great many different ways, and I want to discuss those in relation to their practical importance.

Of course it was true that the vacuum was higher. They showed no blue glow. There was no perceptible part of the current carried by positive ions and there were many factors of that sort, but after all, it does not make the slightest difference in a vacuum tube whether there is blue glow or not. It does not make any difference whether the pressure is high or not, that as a factor in itself is not of the slightest importance.

The practical question depends entirely on the electrical characteristics of the tubes. These devices were used entirely as electrical devices.

The three-electrode tubes were used to control electric power. The two-electrode tube devices were used to rectify alternating current and in some cases to regulate an electric current by means of the filament temperature. The Coolidge X-ray tube was used to convert electric energy into X-rays. In all those cases it was of the utmost importance from a practical point of view to have reproducible characteristics, to be able to get the same result whenever the tube was operated under similar conditions. If a given voltage is applied to the electrodes of a three-electrode tube to each of the two electrodes it is of the utmost importance that you should always get the same current.

Now, this reproducibility is important, not only in taking successive readings. For example, if you make measurements on a tube and you take a series of readings by raising the voltage and measuring the current at each voltage so as to get a characteristic curve of the device, if you raise the voltage in steps in that way up to the maximum and then lower it in steps and you get different readings coming down from what you got going up that device is certainly not reproducible. But reproducibility means more than that. It means that the characteristics shall not only stay constant during the short time that elapsed between the time of the taking of the curve going up and coming down, but it means that the device shall stay constant from hour to hour and from day to day during its life.

In all practical applications of the three-electrode tubes, that factor is very important, because the tube is only part of the outfit that is being used, that is, the tube is part of a circuit and the circuit has to be adjusted to the characteristics of the tube.

For example, if used as a telephone relay it is very important that the tube shall be properly balanced with the characteristics of the circuit. The same is true in all radio receiving sets, particularly the more complicated ones. The characteristics of the tube need to be very definite in order that the whole set may be built around the tube or built to fit the tube. If the tube has one characteristic today and another characteristic another day you cannot build the circuit to fit the tube under both conditions.

There is another important feature in regard to the characteristics of the tube and that is that the characteristics shall be a smooth curve. For example, as you vary the grid voltage suppose the current to the plate changes in such a way that it has a kink at a certain point, a sudden change of direction and slope, such as was common and usual in the old DeForest audion, that means that the voltage on the plate and the voltage on the grid must be carefully adjusted so as to work at that particular part of the curve or at a definite point on the curve because a slight change in voltage on the grid or plate from that value changes the slope of the curve over the working range. So that again the electrical characteristics, impedance of the tube and the other important constants of the tube would vary very rapidly with such factors as the B-battery voltage.

The whole modern development of radio receiving sets has progressed along the line that effects of that sort are to be eliminated. It is desired to have a set which will work the same one day as another, even if the B-battery voltage should decrease a little. We did not want to have tubes that are abnormally sensitive to filament temperature, to B-battery or to C-battery.

So I think I have emphasized sufficiently the fact that all of the useful characteristics of the tube depend upon the volt ampere characteristics in the working range, within the range over which the tube is to be used. If the tube is to be used as a three-electrode tube it must be used on the part of the curve where the current is limited by space charge because it is only under that range that you can change the current by changing the voltage. If you are on the saturation part of the curve the current is limited by the emission from the filament and is not dependent on the voltage on the electrodes, and therefore you have no control over it. Plate voltage or grid voltage will not change the current through the tube, and such a tube is not useful as an amplifier or detector.

So I emphasize also the fact that we are interested in the characteristics over the operating part of the curve. In a three-electrode tube that means on the space charge part of the curve. The saturation part of the curve is of no importance whatever in a three-electrode tube, provided the current that is emitted is sufficient to allow the current to be limited by space charge over the operating range.

We come, therefore, to the reproducibility and the smoothness of the characteristics as the essential qualities that a three-electrode tube must have. The same thing is true of the Coolidge X-ray tube, although there we are operating on the saturation part of the curve and not on the space charge part, but there again it is reproducibility and definiteness of characteristics and smooth curve and emission must vary with the temperature in a definite regular manner.

Having that in mind that those are the only important factors, really important factors in the operation of an electron tube, I think we can analyze better the different tests or the other characteristics of the tubes that distinguish them. For example, the vacuum in the tube, the pressure in the tube.

The pressure does not make any difference in a tube, if the tube has good characteristics, is reproducible and stays reproducible during its life. No one would object to the tube because it had ten microns of gas in it, that would be the last thing to think of. But if it has ten microns of gas in it and that gas changes and the change of that gas causes the characteristics to change in an irregular way, in a non-reproducible way, then the gas pressure becomes important.

The same way with blue glow. If we had tubes that have good characteristics, that are good amplifiers, that fit into a circuit well, and stay balanced in that circuit from day to day, nobody would object to there being blue glow in that tube. It is the last thing that we would think of. It would be taken as a characteristic of the tube. For example, in the Tungar rectifier no one objects to the fact that there is a glow in the gas.

The same is true of positive ion current. For instance, we have the three-electrode test or "the counting of ions" that has been used as a test for the purity of electron discharge. Take the two-electrode tube. It does not make any difference in that tube if there is positive ion current or not as determined by a third electrode, which might be introduced for the purpose of counting the ions. The important point is only, do the electrical characteristics of that device have certain qualities and do they retain those qualities during the life.

This test of the reproducibility and the smoothness of the characteristic curve has, I believe, been emphasized by all those who have testified in this case on the motion and on the priority record. I think it was emhasized by Van der Bijl more than any one else and has sometimes in the record been referred to as Van der Bijl's test and I believe every one else has recognized the importance of it.

MR. HAIGHT: I think, if your Honor please, we are getting off into a field that is not that of the witness to explore. He is now discussing the evidence in the case. I do not know where it will lead us to.

THE COURT: I think he did that to shorten the testimony rather than adding anything to its substance. I think he is not discussing the evidence at length. He is referring to two circumstances and I think probably he has covered all the field that he intends to cover.

MR. LUNT: I think, your Honor, it is simply to identify the situation.

THE COURT: You understand, of course, Dr. Langmuir, that your last reference was to tie things together.

A. (Continued.) All I want to do now is to give names to the different tests so that we can refer to them. The first test we may call the reproducibility test. The second test, and by test I mean a particular characteristic of the pure electron devices which may be used as a means of identifying them—the second test is that as the pressure is decreased the characteristics shall not change as a result of that decrease in pressure. You may call that the pumping test. A third test is the blue glow test.

Now, I would like to point out that these tests are secondary, that is, I mean the second and third ones are secondary tests. A change in the characteristics with pressure is only important in the operation of the tube in so far as it leads to non-reproducibility. I believe that the non-reproducibility is the most essential single characteristic, that is, the reproducibility and the smoothness of characteristics can be stated as the most essential characteristic of the modern high vacuum devices as distinguished from the old.

How are we going to characterize that further? What must be true in a tube in order to get this reproducibility?

If there is gas in a tube that pressure will change. If the gas comes off the electrodes as the electrodes are heated more gas will come off and as the tube is cooled some gas will tend to disappear. If the voltage is raised on the electrodes there will be somewhat of an electrical clean-up unless the electrode gets too hot and then it will go the other way.

In other words, in the devices of the old art, in the DeForest audion, the pressure was continually changing.. It sometimes increased and it sometimes decreased. Both things went on and there was an evolution of gas, water vapor would come off the bulb and be decomposed by the filament and it would generate gas. Gases would come out of the electrodes. Positive ions would bombard the walls and the electrodes and would drive gas off. Those were three cases in which the gases would come out into the space and cause an increase in pressure.

There was vaporization of the metal of the filament causing compounds to be formed which would cause the gas pressure to decrease. The ions formed by the discharge in striking the walls would be entangled in the walls and disappear and it would cause a decrease in the pressure.

These things were going on in the most erratic and ungovernable way in the old devices and that is true of all devices that are poorly exhausted.

If there is a pressure of gas such that the ionization produced by it modifies the space charge, partly eliminates the space charge, and therefore allows more current to flow than would otherwise flow, then any change in that gas pressure will cause a change in the ionization and space charge will be eliminated to a different degree and there will be a resulting change of current.

One way to get rid of that effect is to lower the pressure at such a point and maintain the pressure at such a point that there is not enough positive ionization to have any appreciable effect in neutralizing the electron space charge. Then the current becomes definite. A further lowering of the pressure beyond that point is entirely immaterial as far as the effect on the characteristics of the tube go. It would not make any difference if the pressure is lower than that.

If in a given device at a pressure of one micron, if that is the maximum pressure under operating conditions and if with one micron pressure and a given voltage on the tube the positive ions are not sufficient in number to have any appreciable effect on the space charge, the current will then be definite and will be the same as though the pressure were made zero. Further lowering of pressure will not have any further effect in changing the current.

So that the second test is equivalent to the first test, that is, if you find that a lowering of the pressure produces no effect on the characteristics, then you will get reproducible characteristics, because the change in the pressure is the factor which causes the lack of reproducibility in the old art devices.

And it is because we cannot make that test in ordinary devices that are sealed off that we need to come back to such test as the 3/2 power test. Let me explain that.

If we can pump out the tube and see if there is any further change in the characteristic on pumping out, we make a very good test, but that is not the practical thing to do in a sealed-off tube. We cannot have a tube that is sealed off and tell whether the characteristics stay constant as we are lowering the pressure.

Now, the effect of the pressure is primarily to change the space charge effect as the result of the ionization produced by the gas. We can avoid ionization in any device by going below ionizing voltage. If we lower the voltage to fifteen or twenty volts (at fifteen volts we get no ionization in any device), and if as we raise the voltage we know the law according to which the current would flow in the absence of ionization, and that is generally the 3/2 power law, and then we take the characteristics in a device which contains gas below ionization, it should be the same because the pressure of the gas does not affect the current in the space charge part of the curve as long as there is no ionization. As you raise the voltage above the ionizing voltage and you have some gas present, you will have some ionization and the current will rise above the value that you would get if you had no gas. Let us assume that we have no gas; you will then get the 3/2 power law from below ionization to above ionization. Then, if you have gas you will get the 3/2 power law up to the ionizing voltage and then gradually you will get an increase in current. That represents a departure from the normal curve characteristic of high vacuum. That will mean in general an increased slope. The current will rise more rapidly with voltage than it would if you had an extremely high vacuum in the device.

It is for that reason, so that we can make a comparison between the device when operating with pure electron discharge as compared with what it is when it is not operating with pure electron discharge in the presence of gas,—that we use the law of the tube for the high vacuum.

It is important to know then in a given type of device what the law of the tube is in a high vacuum because then, if we get a departure from that above the ionizing voltage and little or no departure below the ionizing voltage we use that as a means of telling what effect is produced by the ionization.

In other words, the use of the 3/2 power law in that case is practically equivalent to the pumping test where you lower the pressure. The object of lowering the pressure in a given device is to avoid the ionization and thus to see what happens in the absence of ionization.

Suppose you have a tube with 100 volts on the electrode. We get a certain current with a certain voltage. We pump out the gas and the current decreases say 30 per cent. That is due to ionization and not due to pressure of the gas. It is due to the ionization which results from the pressure of gas. If we can avoid that ionization in any other way we would know what effect would have resulted from pumping out the gas. If we can lower the voltage until the ionization stops then we have the same curve as though we did not have the pressure. We have the same effect although we did not pump it out. That is the importance of the 3/2 power law. It enables us to compare the characteristics in the absence of ionization with that in the presence of the ionization.

If there is no difference, that is, if the law is the same as if it was in a perfect vacuum then we can conclude that a further lowering of the pressure would not have any effect on that characteristic and we also conclude that the characteristics will remain reproducible during the whole life of the device; making a measurement going up and coming down tells you that the curve is reproducible during that period of time while you made the measurement.

If you can go further than that and prove that that device is not influenced in any way then you know that you have no effects of ionization.

THE COURT: The possibility of gas subsequently coming in?

A. Yes, being evolved. At any rate, a clean-up may take place in the tube which will cause no effect. You can see from that that a clean-up in the tube may be a very bad thing, in that it may cause a change in the characteristics.

Suppose you take a device and balance it in a telephone circuit while it has gas, and subsequently that gas disappears. The device is no longer balanced.

I might say a few words about the blue glow test. Blue glow results from the impact of electrons on gas molecules, causing them to give out light. It is not essential that there should be ionization, but ionization usually accompanies and greatly increases the blue glow. But in most cases blue glow is in general proportional to the strength of the current, that is, with 100 milliamperes, other things being the same, you will get 100 times as much blue glow as with one milliampere.

Blue glow increases as the voltage goes up. We have spoken about the ionizing voltage. Suppose we consider a gas which has an ionizing voltage of twenty volts. That means that unless an electron has moved through a difference of potential of twenty volts and has acquired a velocity corresponding to that, it cannot produce any ions at all, because there will be no ionization at all below the ionizing voltage.

But if you go slightly above the ionizing voltage, say twenty-one volts, only a very small fraction of the collisions result in ionization. At twenty-two volts a larger fraction; at thirty volts a still larger fraction. So that the ionization begins abruptly at a certain voltage but increases only slowly beyond that.

It is for that reason that in an old tube like the DeForest audion containing a certain amount of gas, you usually do not notice the effect of ionization right at the ionizing voltage. It comes in a little higher than that, five volts, ten volts. The effect begins at the ionizing voltage but it begins by being almost imperceptible. The result is that in most of these devices, ionization first becomes to be important at twenty or twenty-five volts or thirty volts. Then it increased steadily until you get up to about 200 volts or thereabouts, when it reaches a maximum, and under those conditions thirty or forty per cent. of the collisions result in ionization, not all of them even at those voltages.

Therefore, blue glow as a test for ionization does not measure the number of ions produced. It does not measure the effect of the ionization on the characteristics which is the thing we really care about, but it measures something which is related to the voltage in a complicated way and is proportional to the current.

As a result of this blue glow at 250 volts with large current is a very sensitive test you might say for vacuum. And it is so sensitive that with large currents, say 100 milliamperes, that we can be sure that any device that does not show blue glow under conditions of that sort in the ordinary structure—it might be conceivable that you will not get this effect with certain structures—then you know that the ionization is so small that it will not affect the space charge.

On the other hand, if you are working at lower voltages and small currents, there may be enough ionization to eliminate space charge and yet not show blue glow. Blue glow becomes a better and better test the higher the currents you are working with and the higher the voltages you are working with. At low voltages and currents it may be a very insensitive test and it is not necessarily related to the thing that we are interested in, the reproducibility of the characteristics. Only in so far as the ionization which accompanies the blue glow is in sufficient amount to neutralize the electron space charge do we care at all about it.

By MR. LUNT:

Q. 201. Is the 3/2 power test necessarily any proof of the degree of vacuum? It may be that that can be inferred from what you have said, but I do not know that it appears clearly.

A. The 3/2 power law I consider to be particularly useful as a test of the quality of the pure electron discharge devices for the reason that it is a characteristic that tells us just what we want to know. It tells us to what extent the characteristics are affected by gas in the operating range.

We operate in the three-electrode tube on the space charge. The 3/2 power law is a measure of the characteristic on the space charge part of the curve. So that they are both on the space charge part of the curve.

If the gas is present in sufficient quantity to cause a deviation from the 3/2 power law, it of course changes the characteristic of the device, because if there was no gas it would follow the 3/2 power law and a departure from the 3/2 power law due to gas shows that the characteristic has been modified by gas.

That is the value, I think the particular value of the 3/2 power law as compared with the other tests. It does not measure pressure. It measures the effect of the gas on the characteristic, that is, the departures from the 3/2 power law measure the departure of the characteristics from those characteristics of a perfect vacuum.

We do not want to measure pressure in a practical device. To know that the pressure is five microns or one-one-hundredth of a micron does not tell us whether the device is good or bad. We want to know what the characteristics are.

There are deviations from the 3/2 power law when the amount of positive ionization is a certain fraction of the number of electrons per unit volume. You will get certain deviation under given conditions. As you lower the current you lower the positive ionization, but the departure from the 3/2 power law may remain constant. You may get with a low current as great a departure from the 3/2 power law as you may with a larger current.

In the same way the pressure will be different in different devices when they show the same amounts of departure from the 3/2 power law. For example, if we take a device with long distances between the electrodes and we have, we will say, one micron of pressure, we will get a certain amount of ionization in that space and the electrons in passing across that space of say ten centimeters will produce a certain number of ions. If we had that same pressure of one micron and we had a distance only one-tenth as great you will get only one-tenth as many ions formed, but the electron space charge will be the same close to the surface of the cathode.

So that the important element in determining the effect of gas on ionization is not the pressure at all, but it is the amount of gas in the space between the electrodes. For example, if we take electrodes ten centimeters apart with a certain amount of gas, and we put those electrodes closer together, keeping the same total amount of gas between them, we would get the same amount of ionization but we would have ten times the pressure, because there would be the same amount of gas in one-tenth of the space or volume. Do I make that clear?

THE COURT: If that is what you mean, that is not clear. Where do you get the same amount of ionization?

THE WITNESS: If an electron travels a certain distance through gas at a certain pressure, there is a certain probability of collisions that result in ionization and let us say there is a 50 per cent chance that the electron will collide with a molecule in traveling say ten centimeters. If you take the same amount of gas in a smaller volume, you will have to have a larger pressure.

THE COURT: Yes.

THE WITNESS: You will have the same amount of gas——

THE COURT: I missed that. Then I understand now.

THE WITNESS: That is, if you take two electrodes and bring them closer. The important element is the total amount of gas in the volume inside of the electrodes inside space.

THE COURT: I did not know you kept that the same.

THE WITNESS: Not the pressure.

THE COURT: Shall we take our short recess?

(Here a short recess was taken.)

By MR. LUNT:

Q. 202. Had you finished your answer?

A. Not quite. I want to make it clear that if you have a tube with the electrodes close together you can have a much higher gas pressure and still get it to agree with the 3/2 power law, and still get characteristics that are not affected by ionization. For example, in this tube of Exhibit 56, the anode and cathode are very close together. You can tolerate a very much higher pressure, two or three times higher pressure than you could in a device like Exhibit No. 47, where the anode and cathode are two or three times as far apart.

THE COURT: May I ask this: Assume the pressure to be constant and you move your electrodes closer together, do you get less ionization?

THE WITNESS: Less ionization the closer they are together. The more as you put them further away.

THE COURT: The pressure remaining constant?

THE WITNESS: Yes. That goes back then to the days of the old-fashioned X-ray tubes. In the old-fashioned X-ray tubes if you put your electrodes closer together you had to use a higher voltage to get a discharge between them because there is less gas between them to ionize. There is less ionization, and therefore it is more difficult to get a discharge because that discharge depended upon ionization.

Q. 203. Those were Defendant's Exhibits numbers which you have just referred to, are they not?

A. Yes.

Q. 204. Do you wish at this time to talk briefly about some of the causes which mask the 3/2 power law or to say something about it?

MR. HAIGHT: That is a pretty large question.

THE COURT: Read it. (Question repeated.) I assume you won't press that in the presence of objection?

Q. 205. Will you explain briefly some of the causes which affect the 3/2 power law or its manifestation?

A. I have already said that in case there are three electrodes, a modified form of that law should be used, where you take the 2/3 power of the current and plot that against either the plate voltage or the grid voltage, that method of plotting the relationship using the 2/3 power of the current tends to eliminate some of the secondary factors that may influence the relation between the current and the voltage. First of all, the potential of the electrodes may not be what you think they are, because of a contact difference of potential which may amount in some cases to as much as three volts, so that where the voltmeter shows a difference of potential of 15 volts between two electrodes it may actually be twelve or eighteen, and that is a constant amount that would be added to the voltage. If you plot the current against the voltage on logarithmic paper, that constant amount displaces the curve by different amounts at different parts of the curve because of a non-uniform scale; but if you plot the 2/3 power of the current against the voltage a change in the voltage displaces the whole curve laterally, without changing its slope or its curvature. Thus by plotting the 2/3 power of the current, we eliminate effects or errors, which may come in because of the contact potential. On the other hand that factor alone cannot cause the displacement of the curve by more than two or three volts, the magnitude of the contact potential, unless as in some of these cases we are plotting the plate voltage, and the contact potential is not on the plate but on the grid. Then there is the amplifying action or amplification constant comes into between the relationship between the grid voltage and the plate voltage.

Now, another fact that may cause apparent deviations from the 3/2 power law is a voltage drop along the filament, the cathode. However, if we take the voltage from the mid-point of the filament that factor becomes relatively unimportant.

In tubes of special design, deviations from the 3/2 power law may be exaggerated, and particularly is this true in the case of three-electrode tubes. For example, if we had a grid and a three-electrode tube, and a linear filament, a straight line filament, and over one part of the length of the filament we had a coarse grid and the other part we had a fine grid, we really have two tubes in parallel, and if we then put a negative voltage on the grid, you might have a negative voltage enough to stop the electrons entirely in the passages through the grid in that part of the grid where the wires are close together, but they would pass easily through the part where it was coarse. So we begin by getting the current characteristic of one part of the device, and then of the other.

That is one kind of factor that causes variations, that is, a non-uniform structure of a grid causes deviations, particularly at the very lower end of the curve, with small currents. As soon as the grid becomes positive that effect disappears because then the electrons go through the whole of the grid, and it is the average characteristics of the grid that becomes more important.

If the cathode is almost entirely enclosed in a shield, as for example, it was in the Coolidge X-ray tube (indicating), thus if you take a cathode that is at the bottom of a cup-shaped depression, and we measure the volt-ampere characteristics of the anode, we do not get the 3/2 power law, because there the electrons which escape are determined largely by the initial velocities and only a few electrons have sufficient velocity to carry them out into the region where the field of the anti-cathode is effective. On the other hand, if you take exactly the same tube and remove that shield, you get an excellent agreement of the 3/2 power law, so that these are cases where the geometry of the tube may cause departures.

But I would like to say this, that with practically all of the tubes that are used today, the 3/2 power law expresses admirably the characteristics in the absence of gas, and if you put in gas, it causes deviations beginning a little above the ionization voltage and increasing rapidly as you go above that point. The same is true even where the anode and the cathode are of the most varied shapes, out in the middle of bulbs, for example. Take the early experiments that I have already described, where we had two hairpin filaments in a cylindrical bulb. In those cases, the 3/2 power law applies with very great accuracy. I mean within one or two per cent. of accuracy, or something of that sort. There are factors, such as the factors that have been included in the derivation of the equation, for example, the initial velocities of the electrons that cause appreciable deviations, but they do not produce deviations that can be mistaken for the effects of gas. The effects of gas are usually quite unmistakable, if present in important amounts; so that for that reason I believe that the 3/2 power law and the inverse law, the 2/3 power law, constitute by far the most useful test we have that can be applied to a sealed-off device, to tell whether or not the characteristics of that device are modified appreciably by ionization resulting from gas.

Now, that does not mean, however, that the 3/2 power law is a test that you would apply in a factory, or in a laboratory, day by day, as the means of testing the usefulness of a device that you are making. For example, in our own laboratory, when we make or exhaust a tube, we do not stop during that exhaust in order to see whether the device has characteristics that follow the 3/2 power law, because we have the device still on the pump. We could apply the pumping test much more conveniently, but as a matter of fact in the practical manufacture of tubes, the third electrode test, which Professor Millikan described, or the method of counting ions, is by far the most convenient, because if you are making any definite type of device, making that device over and over again, you calibrate that test. You find by experience, after making up several of these devices, or a large number of devices of the same geometry, how good your vacuum needs to be in order to get a tube that is satisfactory, that means a reproducible characteristic, long life and any other factors that you may wish; we find by experience how high the vacuum is and measure the vacuum by the three-electrode test. A certain current is found by experience to mean a certain number of microns of a gas, but it is then necessary to measure the upper limit of pressure with which you could afford to operate the tube. The advantage of this test is that it is made by one measurement. You simply put a definite voltage on each of the two electrodes, and you measure the current. It is a test that can be made while the tube is being pumped out, or at any time afterwards. But it means nothing unless it has been calibrated; that is, unless you know the relationship between the positive ion current that you obtain under these conditions, and the characteristics of the tube that you obtain from that device under operating conditions. As I said before, it would not make any difference if you had a microampere or several microamperes of positive currents obtained under test conditions, if the characteristics of the tube during operation were satisfactory. The usefulness of the tube depends upon the characteristics under operating conditions, and any test for the satisfactory operation of the tube must be interpreted in its relation to those operating characteristics.

Q. 206. I think that the first X-ray tube exhibit which you referred to was No. 22 in the Interference, and a second one was No. 25, which correspond respectively to Nos. 42 and 45 in this case; is that correct? At least as to the original numbers which you find?

A. Yes, Plaintiff's Exhibits 45 and 42.

Q. 207. We will now pass on to the next subject and I will ask you to describe the difference in principle between the operation of a three-electrode tube as a detector, and also as an amplifier, and to compare the behavior, when gas ionization is present, with that when gas ionization is absent.

THE COURT: Compare what?

Mr. Lunt: The behavior.

A. When a tube is used as a detector, a high frequency current is applied to the grid and a constant direct current potential is applied to the plate, and a telephone, for example, or other indicating device is placed in that plate circuit. Ordinarily, the high frequency alternating current that is applied to the grid varies with time, that is, it is modulated so as to increase and decrease in magnitude periodically of an audio frequency, and it is desired to cause variations in the current through the telephone which do not follow the radio frequency applied by the grid, but follow the audio frequency which modulates the high frequency of the grid circuit. Do you understand that effect of modulating?

The Court: Yes, I know what it does, but there are a lot of things I do not know about it.

A. If we have a radio frequency wave with, we will say, one million vibrations or cycles per second, and we cause that to vary in amplitude periodically, we speak of its being modulated; but the frequency remains the same with the amplitude increasing and decreasing again. The time intervals that elapse between a period of maximum amplitude and the next period of maximum amplitude, will be the audio-frequency period; that is, one-thousandth of a second, for example, if we modulated it at a thousand cycles. That is, the radio frequency wave will be at a maximum intensity at a certain time, and then will fall to low intensity, and after one-thousandth of a second, will increase to maximum intensity again.

Now, in order to get audio frequency variations in the telephone which is connected to the plate, we must have changes in the average value of the direct current component of that plate current.

Let me illustrate. Suppose, for example, we have a point A on the characteristic curve, which I now illustrate (indicating). We have a curve, for example giving the plate current as a function of grid volts, and we take the point A of that curve, that corresponds to a definite grid voltage, which we will say is V_1 and the plate current I_1. Now, when the radio frequency wave is applied to the grid, the grid potential fluctuates between the lower value V_2; and the upper value V_3, and in the corresponding way the plate current changes from the value I_2, when the voltage is V_2, to the value I_3, when the voltage is V_3. So we may say that we go at the rate of a million times a second back and forth between the two points on the curve which we may call A_2 and A_3.

Now, if that line between A_2 and A_3 is a straight line, it is seen that the current increases and decreases by the same amount. Therefore, whether you have the radio frequency signal applied or not, will make no difference in the average value of the plate current. That is, if no signal is applied at all, we have the current I_1. If the radio frequency signal is applied to the grid, we have currents that vary from I_2 up to I_3; but since the characteristic line at the point A is straight, the increases and the decreases just neutralize each other, so far as the average current goes, and thus the average current through the telephone remains the same as though no signal were applied. It is true that the current varies a million times a second up and down; but the telephone cannot respond to a million cycles per second, neither could the ear hear the sound even if it were produced with the frequency of a million cycles per second.

If we vary the amplitude of the signal as when we actually do apply a radio frequency signal on the grid, we are merely changing the current so that in one case it stays very close to the value I_1 and in the other case it oscillates back and forth between the value I_2 and I_3; but the average current through the telephone which is the only current that will affect the movement of the diaphragm is practically the same in both cases. Thus the diaphragm is not put into motion at the low frequency with which the modulation is made.

Suppose for example, a thousand times a second you change between having a steady voltage V_1, and the alternating voltage which varies between V_2 and V_3, the total current flowing through the telephone will be the same in both cases, so that it will not cause any motion of the diaphragm, since the position of the diaphragm at any time depends upon the average current flowing through it at that time. The rapid fluctuations of a million cycles do not cause motion of the diaphragm.

The point I want to bring out is that the detector action is zero if the curve is straight, if we are causing fluctuations of voltage, which cause the current to change only over that part of the curve where the characteristic is straight, the sensitiveness as a detector is practically nothing.

On the other hand, if we pass down to a point where we have a voltage V_4 applied to the grid in one case, and in the other case we let the voltage fluctuate between V_5 and V_6, then the plate current changes between I_5 and I_6, when the alternating current is applied to the grid, but it stays steady at I_4, if a steady voltage is applied to the grid.

Now, we see, however, because of the curvature of the characteristic of the curve near the point corresponding to V_4, the increases in current in going from I_4 to I_6 are much greater than the decreases that occur in going from I_4 to I_5, so that the average value of the current while the grid is fluctuating, is considerably larger than the average value of the current when the grid stays at the fixed potential V_4. Therefore, as the radio frequency current increases and decreases in value, there will be fluctuations in the average value of the current through the telephone, and since these fluctuations occur a thousandth of a second apart, and the telephone diaphragm can respond to variations of current that extend over that speed, the diaphragm will be set in motion at a frequency of a thousand cycles a second.

The point I want to emphasize, therefore, is that the detecting action of the audion depends upon the curvature of the characteristic curve, and the curvature may be either an upward curvature or a downward curvature. Exactly the same method of analysis that I have applied to this point V_4 could be applied to point A_7 where the curvature is a downward curvature.

In general, therefore, with a vacuum tube of the audion type there are two portions of the curve where there is good detecting action, a place where the upward curvature is the maximum, and the place where the downward curvature is the maximum, and there is a point in between where the curvature is the minimum or zero, where the detecting action is small or entirely absent.

On the other hand, we have just opposite considerations to take into account if we are dealing with the amplifying power. First of all, let me say that when we use a tube as an amplifier we do not apply a radio frequency to the grid, but we apply the audio frequency, or we apply to the grid the same frequencies as the frequencies which we wish to observe.

In the case of the detector, we apply one million cycles to the grid when we wish to observe, say, about one thousand cycles. A detector converts waves of one frequency into waves of a lower frequency which represent a modulating frequency that is applied to the high frequency signal; whereas, in the case of amplification we have a certain signal at a certain frequency and we wish to convert it into another identical frequency, the same kind of wave, except more energy. To do that we wish to apply certain voltages to the grid and get as large a change in current as we can.

Therefore, we pick out a place where the slope of the curve is the greatest, and, in general, the point where the slope of the curve is the greatest is the point in the curve where it is straightest. At the lower end of the curve it is flat and increases in slope to a certain point and then decreases in slope again. The steepest place is where it does not curve one way or the other and therefore, it is very nearly straight.

Thus the amplifying power of a tube is measured by the slope of the curve, the steepness of the curve. The detecting power is measured by the curvature and not by the steepness. The greatest amplifying power for small signals, of very low intensity at least, occurs at a portion of the curve where the detecting power is the least.

Mr. Lunt: To avoid confusion, I would like at this point to offer this explanatory diagram in evidence as Plaintiff's Exhibit 167.

(Received in evidence and marked "Plaintiff's Exhibit No. 167." *See Volume IV, Plaintiff's Exhibits, page 49.*)

A. (Continued.) If we put gas into a tube of this sort the curve slopes upward much more markedly above the ionizing voltage, and I might indicate here, for example, by a dotted line, the curve that might be observed in the case of gas ionization. I will mark that by the curve S. T. U.

There is another portion of the curve where in the neighborhood of S. there is a high curvature, that is, when ionization begins or shortly after ionization has begun, where the curve curves upward rapidly. That, therefore, will be the region where the tube becomes a good detector.

Then at the upper range, just before the curve becomes saturated at the point T, will be a place where the curvature is very high and there will be another region where such a tube may be used as a good detector.

In between the curve has a much greater slope than it would have if there was no gas present and since the amplifying power depends primarily on the slope, the amplifying power of the tube will in general be much increased by the presence of gas. That has not only made the detecting action greatly increased but the amplifying action of the tube will be greatly increased but the range over which it becomes a good amplifier is very much decreased and it will require a critical adjustment to get the best amplifying power, just as it will require a critical adjustment to get the best detecting action.

To illustrate some of these points I would like to show you some curves that I had made with standard tubes that have been manufactured by the General Electric Company. These first two curves are taken on a UV-201 tube.

Q. 208. May I ask you, doctor, to indicate these different curves by letters or numbers so that we can distinguish them.

A. I will take first A. I will mark them A, B,—I see they are already marked. I will mark them A, B, A^1, B^1, and D. Now curve B or the family of curves on sheet B were taken with a UV-201 tube, which is a high vacuum tube. In these curves the 2/3 power of the current is plotted as ordinate and the plate voltage from zero up to one hundred volts is plotted as abscissæ, and the five curves correspond to different fixed grid voltages, —2, —1, 0, plus 1 and plus 2 volts.

Curve A is a similar set of curves obtained on the same tube but with a lower filament temperature, so that the total emission is about one milliampere.

It will be noticed that these curves, particularly those with the positive grid voltages, are straight lines, and they are over the larger part of their range parallel straight lines; only at low currents, which are small fractions of a milliampere, do the curves with the negative grid voltages tend to flatten out slightly, and that is due, I believe, to the fact that the grid is not quite uniform in mesh, so that some electrons are able to get past the grid, a very few electrons are able to get past one part of the grid when it is at such a negative voltage that electrons cannot get through the other parts of the grid.

The same is generally true of the curves with the lower filament temperature. They are essentially parallel straight lines until they approach saturation and then the current flattens out to approach saturation value.

We will now take a tube of practically identical structure—they were made in the factory about the same time, and are as far as we can tell almost identical structurally, but this is called the UV—200 tube shown on curve sheets A^1 and B^1. This tube contains sixty microns of argon which was deliberately put into these commercial tubes for the purpose of making them better detectors for radio signals. A large number of these tubes have been sold because of the better detector action of these tubes for radio signals.

If we look at the family of curves obtained from these we find that up to fifteen volts we again get practically a series of parallel straight lines, but beginning at fifteen volts they curve suddenly upwards, characteristic of ionization.

That is, these curves without ionization would follow out along the lines which I have indicated in dotted lines, and the sudden upward departure beginning at fifteen volts and becoming very large, indeed, at a little over twenty volts, is the normal and characteristic effect of gas ionization, showing that the limitation of the space charge is rapidly being removed and these currents would rise within a few volts up to saturation value no matter how high that might be. That is, no matter how high the electron emission from the filament may be, the curves would rapidly rise up to that saturation value. Of course, practically the tube might very rapidly become overloaded and injured.

Thus these tubes in their ordinary operation were limited to a very definite and narrow range of voltage running from about eighteen up to twenty-three or twenty-four volts, but in that region they are excellent detectors because of the high curvature, and excellent amplifiers, very much better amplifiers than the high vacuum tube at the same voltage.

Now, on curve A^1, curves that were taken with this gas tube when the emission was lowered to about one milliampere——

Q. 209. What is the number of that tube?

A. UV-200. No. 2 was the number given to this tube for the test. They were taken right out of stock and the pressures sixty microns are determined by the third electrode test, measuring the positive ions, these tubes this type of tube having previously been calibrated for use in that way.

Another tube was taken of the type of UV-200, which contained an unusually low pressure of gas for these tubes, nine microns, and during the course of the measurement of these tubes which ran up to fifty volts, the gas pressure cleaned up until there was only four microns of gas at the end of the test. For that reason, and as I do not know how the pressure changed in between, these curves are not strictly comparable on the part of the curve where there is ionization. But again we see the sharp upward bend of these curves beginning very definitely at about fifteen volts and running up as the voltage increases to thirty volts where the maximum slope is obtained.

But the currents become many times greater than they should be if the current followed the 3/2 power law over the whole range. I would like to point out that where on this curve the current appears to be twice its normal value, it really means about three times its normal value, because we have only plotted the 2/3 power of the current and I would have to put on these curves, on one margin, the currents of milliamperes so that it can be seen just how large the currents are and how large the deviations are due to the effect of gas.

I think everybody recognizes that in detector tubes gas greatly increases the sensitiveness as a detector in those parts of the curve where the curvature is made abnormally large by the presence of gas. There is a critical adjustment of any one of several factors. The plate voltage or the grid voltage or the filament temperature can usually be adjusted and all three can be adjusted to give the point of maximum sensitiveness as a detector.

But the amplifying power of the tube is also increased in a similar way by the presence of gas.

I have here taken some data on the amplifying power taken with the UV-200 tube and the 201 on this curve which I will mark E. We have plotted there as ordinate the millivolt amperes output plotted against the millivolt plate input when there is—1 volt on the grid. It will be seen that the tube which contained gas, which is the UV-200, shows a very great increase in sensitiveness as an amplifier at a plate voltage of about 27 volts, and that with voltages above 30 volts, it is a poor amplifier, poorer than if it had good vacuum. This amplifying power becomes higher beginning at about 15 volts.

The amplifier power of the high vacuum tube starts in gradually and increases very steadily without any critical points. By the time voltages of 65 volts are reached, the amplifying power becomes as great as that which was observed with the gas tube at 27 volts, and that illustrates what we do today with these tubes.

Although it is possible by means of gas to get high amplifying power, you can get high amplifying power with a high vacuum tube by going to higher voltages and since the high vacuum tube will stand the higher voltages, you can then get a curve which is uniform and has a uniform slope and this is a very much more desirable thing to do.

Besides that you can use your tube over much wider range of voltage and power input without getting appreciable distortion.

By The Court:

Q. 210. I miss why you get the same amplifying power at 65 in the vacuum tube as you do at 27 in the gas tube?

A. Amplifying power is represented by the ordinates in this case, the vertical distance above the axis. When the plate voltage is 65 volts the ordinate in this case is 3.4, which is a little greater than the ordinate of 3.16 for the gas tube at a voltage of 27 volts. You have more amplifying power with the high vacuum tube at 65 volts than you have with that at a lower voltage, say, for example, 27 volts. The amplifying power of the gas tube is 3.18 as compared with less than 0.5 for the other one.

That is, it is nearly six or seven times—the gas tube is nearly six or seven times better as an amplifier at 27 volts, but you can make up for that by going to a higher voltage on the plate.

Still another curve was made for a comparison of the amplifying power of these two tubes. In fact, a third tube was also tested, a gas tube, using a Western Electric Company amplifying test set that we got a good many years ago. We have not used it within recent years, but we resurrected it for the purpose of making these tests and the only object in using it is that it gives the "gain in miles," which has frequently been spoken of in this case.

It shows practically the same thing, that at voltages of 24 or 25 volts, one of the gas tubes shows a maximum amplifying power which falls to practically nothing at 30 volts; another gas tube increases very greatly in amplifying power and goes off the scale of the instrument, that is more than thirty miles at 28 volts; whereas, the high vacuum tube showed a steady increase in amplifying power as the voltage was raised.

Both the gas tubes within a certain range of voltage showed greater amplification than the high vacuum tube. The curve is not very smooth, because with this instrument it is a step-by-step instrument, so that you can only get certain definite miles gain and you cannot measure fractional miles.

By Mr. Lunt:

Q. 211. Did you give the designation of this sheet? A. It is marked F.

Mr. Lunt: I would like to offer in evidence these various sheets and have them marked collectively. They are explanatory diagrams.

The Court: Do you want to reserve for the record that Dr. Langmuir will make some additions?

Mr. Lunt: Yes. I would like to reserve the right to have the figures for currents supplied to the diagrams. I think it would be of help to all of us if we will also reserve the right to ink in these curves.

(The said sheets were received in evidence and marked as follows):

(Diagram A marked "Plaintiff's Exhibit No. 168." *See Volume IV, Plaintiff's Exhibits, page 50.)*

(Diagram A^1 marked "Plaintiff's Exhibit No. 168-A." *See Volume IV, Plaintiff's Exhibits, page 51.)*

(Diagram B marked "Plaintiff's Exhibit No. 168-B." *See Volume IV, Plaintiff's Exhibits, page 52.)*

(Diagram B^1 marked "Plaintiff's Exhibit No. 168-C." *See Volume IV, Plaintiff's Exhibits, page 53.)*

(Diagram D marked "Plaintiff's Exhibit No. 168-D." *See Volume IV, Plaintiff's Exhibits, page 54.)*

(Diagram E marked "Plaintiff's Exhibit No. 168-E." *See Volume IV, Plaintiff's Exhibits, page 55.)*

(Diagram F marked "Plaintiff's Exhibit No. 168-F." *See Volume IV, Plaintiff's Exhibits, page 56.)*

By Mr. Lunt:

Q. 212. In a tube of the character of the Fleming valve does the rectifying property of the tube, which enables it to detect wireless waves, depend necessarily on high vacuum?

A. The Fleming valve depends simply upon its rectifying ability to detect radio signals. It depends on the fact that the characteristic can rise above the axis but not below the axis and therefore it necessarily has a high curvature at some point between.

Below a certain voltage there can be no current flowing through the device. Above a certain voltage the current increases rapidly. In between there must be a point where the curvature is high.

Radio signals received are of very low voltage, giving voltages far below the ionizing voltage on the device, so that there will be no ionization within the device even if there is a large amount of gas present.

The rectifying action does not in any way depend upon the presence of gas or upon the absence of gas. It depends entirely upon the fact that the cathode cannot emit electrons except when there is a positive field to draw them away. No current of electrons can pass across from one electrode to the other if the anode is of negative potential.

Only if such high pressures of gas are present that they actually collide with the electrons to such an extent that they seriously impede the motion of the electrons would the presence of gas decrease the effectiveness of the device as a detector. At pressures of 100 microns or more the electrons will make several collisions with gas molecules in passing across the device. So that pressures of 100 microns or more would be somewhat deleterious, but there is no advantage in the device of the character of the Fleming valve to go to pressures of less than 50 microns.

Q. 213. Will you discuss briefly the matter of anode bombardment in thermionic vacuum tubes and point out whether or not heat production is in all cases necessary to disengage gas?

The Court: This is in the operation of the tube?

Mr. Lunt: In the preparation of the tube.

The Court: I see.

Mr. Lunt: That was the point that I had more particular reference to, but the phenomenon might appear, I suppose, in the operation.

The Court: That is the reason I asked. Dr. Langmuir explained it to me, or Mr. Davis, rather, at recess yesterday, and I was wondering whether bombardment at any time plays any part in the operation of the tube. I do not know that it does, but I have not been told. If this has not anything to do with the case, you may omit it.

Q. 214. Will you please clear up this point which his Honor has mentioned?

A. When electrons flow through a metal they meet extremely little resistance. They are already moving in the metal at room temperature and the difference of voltage applied between the ends of a piece of wire causes them merely to drift. They are already moving in all kinds of directions. A little voltage applied tends to make more drift one way than the other, and results in the transfer. That is not accompanied by any large evolution of heat.

For example, suppose an electric current flows through a tube at say 100 milliamperes. The passage of that current through the electrodes and through the wires leading to them will not appreciably heat them.

The electrons in the hot cathode evaporate out, tend to evaporate out, but if there is no electric field which tends to draw them away they will go back again, the same as if you had a kettle of hot water on the stove. Steam will be coming off, but it will be condensing back and unless you have an opening for it to get out there will be no cooling effect and no net evaporation.

If you draw off the electrons from the hot cathode they do not return back to the hot filament and you get a cooling effect due to the evaporation. It actually cools the cathode but not very much. It is an effect which can be measured.

When those electrons get out into the space and pass across the space they may be accelerated and set into very rapid motion by the pull of the positive charge on the anode if the anode is positively charged.

For example, suppose the anode is charged to a positive potential of 100 volts. Then the electrons moving through that potential are continually set into more and more rapid motion just as a body falling under the earth's gravitation starts in moving slowly and continually accelerates and the energy is stored up in the form of kinetic energy.

The electron acquires kinetic energy. When it is finally brought to rest on the surface of the anode all that kinetic energy is converted into heat. Electrically we know just how much heat can be produced because it is the product of the current times the voltage. Watts is equal to volts times amperes. If we have 100 milliamperes of current, that is one-tenth of an ampere, and 100 volts, the product of those two is ten watts.

There will be liberated at the anode ten watts of energy just as though that anode were in the form of a fine filament which could be heated with ten watts of energy. But in order to heat it in the form of a filament it would have to be made of small cross-section, so that its resistance would be high. If it is in the form of a plate the passage of one-tenth of an ampere through it would not appreciably heat it.

We speak of that as bombardment by electrons, because the electrons give up their energy just as a projectile gives up its energy when it strikes a wall. In the exhausting of tubes and in the operation of vacuum tubes the anodes or any positively charged electrode which takes up electrons becomes heated as a result of this electron bombardment and it becomes important to inquire how strongly it is heated. That depends on the energy.

Suppose we take for example an old-fashioned audion, an old DeForest audion. Suppose the filament takes five volts and it takes four-tenths of an ampere of current. That is two watts of energy put into the filament. That energy is radiated from the filament into the space around and a certain amount of it is intercepted by the two plates, we will say one-third of it may be intercepted by the two plates or one-sixth by each one. That will be one-third of a watt that will be intercepted by each of the two plates, and that will tend to heat those plates, and in vacuum it heats them quite a good deal, that is, probably to two or three hundred degrees Centigrade—just the radiation from the filament.

Now, besides that fact, during the operation of the tube there is a certain amount of energy generated by the electron current that flows. Suppose we have one-half of a milliampere of current, and suppose we had fifty volts, that is, 0.025 watts, which is less than one-tenth of the energy which is radiated by the filaments and intercepted by each of the plates. So that the total energy of that discharge of half a milliampere and fifty volts is negligible compared to the heating due to the radiation from the filament.

So that bombardment, although it is of the same kind as bombardment that could be used for heating the electrodes, is negligible in quantity and without appreciable effect on freeing the electrodes from gas.

On the other hand, if you have, for example, as mentioned yesterday, in this audion No. 2, during its operation or during the measurement of the characteristic of the audion, 15 milliamperes at 250 volts, the product of that is 3.7 watts. 3.7 watts as against 1/40 of a watt is 150 times more energy liberated on the plate.

That would heat those anodes only moderately, 3.7 watts, because the energy used in an ordinary filament would be of the order of thirty or forty watts to raise it to incandescence, for example, or fifty watts would be used—I do not know the exact figures and I think they are in Mr. White's notebook—the actual energies used in raising the anodes to incandescence, while they are run during the baking out of the tube.

I want to point out that it takes a great many watts on a small electrode to heat it even to a moderate heat. Energies of a few hundredths of a watt are not of any importance in that regard.

Now, there also occurs in tubes such as the De-Forest audion positive ion bombardment. If there are positive ions in the gas, that is, if there is ionization of the gas there will be a certain number of positive ions produced. And those positive ions will usually go to the cathode and if the glass walls are exposed they will also go to the glass walls and they strike the glass walls, having fallen through a considerable difference of potential, so that they have relatively high velocity by the time they strike the glass walls, since the glass walls as well as the cathode will be negatively charged, because the electrons flow so easily to them that they give a negative charge to the walls just as there is on the cathode. The positive ions strike the cathode and strike the walls. They cause a slight heating of the walls that is not very important, except in some devices like the mercury arc rectifier, when it is important.

But they bombard the walls, and I believe even with no heating of the walls (thus, the temperature of the walls may be very low, they may be cooled with ice, for example); bombardment by the positive ions causes the liberation of gas. For example, in the mercury rectifier tube or mercury lamp, if it is cooled with ice, the bombardment is much more severe than if it is allowed to be at room temperature, and it causes an actual disintegration of the glass itself, and it will wear the glass down. I have seen positive ion bombardment so severe in some cases that it has actually worn the glass through, until the air leaked in or where it had worn it so thin that it could no longer hold the atmospheric pressure.

The positive ion bombardment will liberate gas from the surface, and it may do that even when there is little positive ion bombardment, if the gas has not been properly baked out. In the same way the electrodes that have not been properly baked out, may have gas liberated by a very moderate amount of positive bombardment in the tube.

With very high voltages such as exist in X-ray tubes and even at several hundred volts, positive ions may be driven into the glass with such velocity that they actually penetrate the glass and therefore are removed from the space.

Now, just one other point, and that is, that the positive ion currents that can be obtained, are always in these devices very, very small compared with the electron currents, even if there are enough positive ions to neutralize space charge completely and allow the current to run up to saturation, for if you neutralize space charge entirely nothing else limits the current. Under these conditions the currents carried by the positive ions will in general be of the order of 1 per cent. or less of currents carried by the electrons. The reason for that is that the positive ions, even with the same force, move 100 times slower than the electrons, so that although you have as many positive ions as electrons in the space (where the space charge has been eliminated as when you have no space charge), since the positive ions are moving 100 times slower than the electrons, they carry much less current, because the current measures the density multiplied by the velocity with which they are moving. So that even in a mercury arc rectifier, as for example, under the conditions that Dr. Arnold spoke about, where he had his auxiliary electrodes bombarded by positive ions, he having put negative voltage on these electrodes (in that case he used 300 or 400 volts), he got only a few milliamperes of current, whereas when he baked out his anodes by electronic bombardment, probably fifteen or twenty volts was effective in causing amperes of electrons to move, so that in such cases we will have a high current at low voltage. We may get the same amount of energy in other cases by the reverse.

Q. 215. I think you have overlooked, or may have overlooked one portion of my question: Is heat in all cases necessary, or is some peculiar effect of bombardment which makes it unnecessary in some cases to operate to secure a diminution of gas?

A. From the experiments that I described yesterday, which were carried on by Mr. Sweetser, before Mr. White built audion No. 2, I became convinced at one time that the impact of electrons on a metal electrode, caused the evolution of gas, and therefore concluded that if a pump were operating at that time, the ~~gas~~ could be removed. That is, the impact of electrons even without heating the electrode, appreciably could be used to remove gas from the electrodes.

I now think that I was entirely wrong in that conclusion, and that I was led astray by the fact that I did not recognize that the gas was liberated not by the impact of the electrons on the surface of the electrode, but by the small number of positive ions formed by the discharge in the liberated gas—by the positive ion bombardment that accompanied the discharge. That is, you may have an electron current which is accompanied by a small amount of ion current. The positive ion current although small in amount, may be enormously more effective in causing the evolution of gas from the walls and the electrodes, than the electron current is.

I think that the electron current in itself does not cause any evolution of gas from the electrodes and therefore can not be used as a means of freeing electrodes from gas unless that electron bombardment heats the electrode and I think that heating in any manner to the same temperature and for same time, would be just as effective as the electron bombardment.

Q. 216. Now, referring to the matter of getting rid of gas from the anode of a tube, will you explain the degree of effectiveness to be expected from the use of heat applied externally to the bulb without internal generating heat in any manner?

A. Baking out a tube containing metal electrodes to the highest temperature that the glass will stand, is entirely ineffective as a means of freeing the electrodes from gas, to a degree sufficient to be useful in making a pure electron discharge device. That tube I spoke of yesterday, with the metal electrodes, that first audion that we built with the plates as the anodes, was the first thing that convinced me of that fact. That tube was baked out at 425 degrees for an hour and then allowed to cool, and the filament was baked out, but as soon as we applied voltage to the electrodes, voltages below 250 volts, and drew the appreciable electron currents, we had clear evidence of ionization. In other words, heating to 425 degrees for an hour, which is really a very severe heating treatment of the bulb, did not make it possible to operate that device as a pure electron device, because gas is immediately evolved as soon as the device is used.

Now, I have had many other occasions to notice that same phenomenon. In this case on the motion to dissolve, I believe I constructed a tube of that character and made a tube with a nickel anode, a nickel cylinder, and put into it a tungsten filament, and we baked out that tube at high temperature for, I believe, about an hour, using liquid air, with a liquid air trap below the lamp, and using, I think, a condensation pump, that is, a mercury vapor pump, a very rapidly operating pump. In other words, we used all the knowledge of the year 1920 or thereabouts, 1919 it may have been, to get a good *vacuum* in the tube, and we also flashed a filament to get the gas out of a filament, and the device was sealed off; but immediately before we could measure the first characteristics of the tube, just as soon as we raised the voltage above the ionization voltage, there were very marked evidences of gas ionization. The resulting curves are given in the record on that motion to dissolve.

Q. 217. I would like now to call your attention to the Lilienfeld & Rosenthal paper which I think is Defendant's Exhibit No. 31. If you have a copy of that paper available, will you look at that portion of the paper referring to the auxiliary discharge, making use of the hot cathode and explain how the same operates, and what are the surrounding conditions in your opinion?

A. In this paper as in the first paper by Lilienfeld & Rosenthal, there is given a diagram showing the four electrodes of this tube. That is, the X-ray cathode and the anti-cathode, or target; and then the auxiliary anode and cathode. It is, I think, recognized by every one that the X-ray part of this tube, that is, the discharge between the cold cathode and the anti-cathode or target, depends absolutely upon positive ionization. That is, no electrons can get out of the cold cathode, except as the bombardment of that cathode by positive ions, and the positive ions can come only from the ionization of gas in the tube.

Now, when in this tube it is desired to get soft rays, as is stated in the paper that just follows by Rosenthal, the current of 180 milliamperes is passed between the auxiliary cathode and the auxiliary anode, and the voltage is said to have come from the city supply line; and in Germany, that means 220 volts, as that is the usual voltage, and the current is regulated by a resistance control in that line.

The voltage available, that is applied between the auxiliary anode and cathode, is less than 220 volts, depending upon the magnitude of the resistance, that is, in series. Assuming that voltage is 200 volts, we can estimate from the geometry of this tube how much current could flow over to the anode, if the current is limited by space charge. I can also tell from my own experience with high vacuum tubes, the order of magnitude of currents that can be obtained from hot cathodes to cold anodes, with distances such as those that are described here; and I find that it is utterly impossible to account for any such currents as 180 milliamperes, except by assuming that the space charge was eliminated by positive ions, or partly eliminated by positive ions; that is; a current of 180 milliamperes is many many times larger than a pure electron discharge current that could flow across a tube of that character.

Now, just to show the kind of difficulty that you get into if you try to account for these currents as a pure electron space charge current, let us make what my experience has taught me to be an equivalent construction. Assuming the bulb to be five or six inches in diameter (the ordinary size of an ordinary X-ray tube, which is about seven or eight inches in diameter), the cathode appears to be about two centimeters long, and the distance between the cathode and the nearest end of the anode is well over a centimeter, or a centimeter and a half or so, and certainly the average distance between the cathode and the near end of the anode, can be taken as two centimeters. The larger part of the anode is at a much greater distance than that.

Now, just assume that that distance is about two centimeters, and assume that the effective area of the cathode and anode are three square centimeters, and that we can apply the space charge equation that applies to the parallel planes. Then substituting into that equation the voltage of 200 volts, you can calculate that the current will be five milliamperes.

Now, of course the geometry is not exactly that. These are not parallel planes, but that would not affect the order of magnitude. There were many factors which would tend to make the current much less than that, if the current were limited by space charge. For example, the whole surface of the bulb, the very large surface of the bulb, is going to be negatively charged even with respect to the cathode, and that is going to add to the effect of the space charge and tend to decrease the current.

For example, suppose, however, you say that the area of three square centimeters is less than the effective area of the anode (I really think that would be the best value to take for the effective area), the question arises as to how big you would have to take the area, in order to get 180 milliamperes. Well, you find you would have to have about 100 square centimeters, that is, the anode and cathode would each have to be 100 square centimeters in order to give you the current at that voltage. But that is utterly impossible, because neither the anode or cathode have anything like that area.

I may also say that my own experience, with a large variety of different kinds of tubes with different kinds of geometries, and currents of only 200 volts, tells me that we get voltages of a few milliamperes under conditions of this sort, two or three milliamperes, up to five or six, or something of that sort, and that you can not possibly get currents of 180 milliamperes limited by pure electron space charge at any such voltage as 200 volts.

That is one factor that indicates to my mind positively that the Lilienfeld X-ray tube could not have had the currents even in the auxiliary circuit limited by electron space charge independently of positive ionization. The positive ionization was needed as much in the auxiliary circuit as in the other X-ray circuit to make that tube work.

There is another factor that makes me feel absolutely sure that that tube had to have positive ionization for its operation even for the auxiliary circuit, and that is this fact: There is in this tube a cathode, a cold cathode of the X-ray discharge, and that cathode is negatively charged to some thirty to fifty thousand volts. This voltage is used to speed up the electrons, so that they will strike the anti-cathode. This must be negative to say 50,000 volts. Now, we know, and I know from my own experience, that putting my hand on the outside of those tubes in November, 1912, and connecting them to 250 volts shop line, completely stopped the current. I could stop it with the finger held near the bulb.

Q. 218. What do you mean by those two?

A. I mean the three lamps that I exhausted on November 19th. Here we have a much worse case. We have an electrode inside the bulb at a potential of minus 30,000 volts that would have absolutely stopped any pure electron discharge between the other electrons in the bulb. It is essentially like a grid with minus 30,000 volts, which would have stopped any current that might have flowed from the hot cathode to the auxiliary anode.

If, however, there is gas in the tube, and of course, we know there is gas, we know there would have to be positive ions, to have the tube work at all;—if there is sufficient gas to partly neutralize the space charge in the auxiliary discharge with the currents that flow from the hot cathode to the cold anode, then you will have a *screening action.* My work in Schenectady for the last three years has been very largely a study of this phenomenon in connection with mercury vapor discharges, the screening action of gas ionization as effecting the charge on a given electrode.

For example, I can illustrate by this: Let us suppose for example, that we have in this bulb ionized gas so that the space charge is largely eliminated. For the sake of illustration, let us assume that positive and negative ions are present in equal numbers.

Now, we put 10,000 volts negative on the cold cathode. The effect of that is to draw the positive ions towards the cathode and to push back the electrons so that the electrons that are moving around in this space that have come from the hot cathode, are pushed away from that electrode, and there is therefore a certain volume near the cathode from which the electrons are excluded, but the positive ions are not. The positive ions are moving into that region.

Now, as that electron atmosphere is pushed away from the cathode, by gradually increasing the voltage on the cathode, the amount of positive charge within that volume from which the electrons are excluded, gradually increases, as its volume increases, until finally the total positive charge in that space becomes equal to the negative charge on the electrode. Well, then, they neutralize one another so that at the edge of this region which I have called by the name of sheath (the positive ion sheath is the region where there are positive ions only) at the outer edge of that sheath where the electrons are no longer repelled, there is *no field* due to the cathode and it is for the reason that there is no field that the electrons are not repelled. If the field extended beyond that, electrons would be pushed still further out.

So we find always in ionized gases, and I have studied them at various pressures, with a very small fraction of a micron, and with high and low current densities, that if you have an ionized gas and put a negatively charged electrode into it, it becomes surrounded by a sheath beyond which the field of that electrode does not extend at all; so that the field is screened off from the other electrodes in the tube by the positively ionized atmosphere that accumulates.

We know in this device that we have positive ions streaming towards the cathode, because that is the way the tube works, and what I wish now to point out is that these positive ions not only cause the cathode to work as an X-ray cathode, but it screens the auxiliary cathode from the negative charge on the cathode, and make it possible for *that* to work. It is only because of that screening action that it would ever be possible to get any electrons at all out of the hot cathode in the neighborhood of another electrode charged by 20,000 volts.

There are thus two phenomena that I understand perfectly well and have worked on for years, that prove to me conclusively, and it is my opinion, that the auxiliary cathode in that device depends upon positive ionization for its action, just as much as the X-ray cathode or cold cathode did.

Q. 219. I have one very short question I would like to ask you before we leave this subject. Will you compare the magnitudes, and do so very briefly, of the degree of vacuum in the old style X-ray tube, and the modern X-ray tube, operating with a pure electron discharge?

Mr. Haight: This invention does not relate to X-ray tubes, I understand. That is immaterial.

Mr. Lunt: It does not relate, your Honor, to specific styles of X-ray tubes, but the X-ray tube which I referred to as the modern tube, is a tube which operates with a pure electron discharge, and to that extent is an exemplification.

THE COURT: I think the X-ray tube is possibly not so far removed from the subject matter of the invention as to make it wholly irrelevant, so I overrule the objection.

A. In the old-fashioned X-ray tube, the positive ion bombardment was essentially to cause the electrons to pass from the cathode, and that, of course, required gas. Now, in the old X-ray tubes, there was gas in the electrodes. They usually used an aluminium cathode which had never been baked out, and which was just loaded with gas. It was heated when the tube was heated, during bake out, and it became heated somewhat by the passage of current through the tube, while the device was on the pump, but it never became baked at all in the sense in which we bake out electrodes today, so that during the discharge bombardment of the cathode by positive ions caused the liberation, practically instantaneous liberation of large quantities of gas right from the surface of the cathode during the operation of the tube. At the same time, the passage of the discharge with these high voltages produced positive ions, which also were at high velocities, and were driven into the glass, and to some extent driven back into the electrodes, so there was a balance between the gas evolution and the gas consumption, or the gas removal by driving into the glass.

Now, at those high voltages the gas driven into the glass did not all come back: very little of it came back during the operation of the tube. The residual gas in the tube at the time of pumping was a negligible factor compared with the gas that came off from the electrodes during the operation of the tube. The tube could be pumped down to a good vacuum. I mean below a micron, if you wished, and the first time you put on high voltage, the gas would be evolved from the electrodes, more or less, as it was needed, and the moment the discharge started, the pressure would come up to several microns.

Now, if those electrodes were baked out, as they gradually became during the operation of the device itself, the X-rays became more penetrating, and both the cathode and the anode became more and more heated, and they gave off larger and larger quantities of gas. But the gas was absorbed gradually, or became consumed by being driven into the glass. There finally came a time when the gas evolution was no longer sufficient to keep the discharge going.

Now, then, they had devices for introducing gas, and these would help out for a certain length of time, but finally the tube would stop even then. Even putting in considerable quantities of gas, you could not get the tube to operate for more than one exposure, lasting perhaps a couple of seconds. Thus the tube would start out in the beginning by being a soft X-ray tube, and at the end, during one exposure, of maybe one second, it would become very hard, and you could then not get a discharge through it lasting long enough for the X-rays that had been generated to take a photograph. That was said to be a cranky tube. The pressures in that tube that were necessary to keep a discharge going after the electrodes became at all deficient in gas were of the order of 5 to 10 microns.

In the beginning the tube would operate with somewhat lower pressure gas, for then the gas was evolved from the electrodes as the discharge passed and the vacuum during matters of seconds would change manyfold. As there were enormous changes in the vacuum that would take place almost instantaneously.

In the Coolidge X-ray tube, on the other hand, its is very important to get rid of the bombardment of the cathode by positive ions, because such bombardment disintegrates and destroys the cathode very rapidly. The ordinary vacuum in the Coolidge X-ray tube is of the order of 0.01 micron, that is, several hundred times better vacuum than in the old-fashioned X-ray tube.

(Whereupon, at 6 P. M., adjournment was taken until Wednesday, November 3, 1926, at 10 o'clock A. M.)

U. S. District Court, Wilmington, Del.,
Wednesday, November 3d, 1926,
10 o'clock A. M.

FIFTEENTH DAY.

HON. HUGH M. MORRIS,
U. S. District Judge.

Appearances: As before.

IRVING LANGMUIR, resumes the stand.

DIRECT EXAMINATION (Continued).

By MR. LUNT:

Q. 220. I will ask you if you have read the deposition of Lamont and of Mrs. Beck offered on behalf of the defendant in this case, and I believe referred to as part of the San Francisco depositions; and do you understand the state of facts and procedure under which the DeForest tubes therein referred to were exhausted?

A. Yes. I have read the deposition and I understand the facts concerning the exhaustion of these tubes.

Q. 220a. If this state of facts and procedure correctly represents what actually occurred and what was the apparatus used as set forth in the deposition, what is your opinion as to the degree of vacuum which was obtained in the DeForest tubes by following the procedure outlined and would the tubes operate as pure electron discharge tubes? In giving your answer, will you please state the facts upon which it is based?

A. The method of exhaust that is described in Mrs. Beck's deposition and is referred to again in Mr. Lamont's deposition was a very crude exhaust using a rather poorly made Springel pump. There was no attempt described in the deposition to remove mercury vapor, in fact it would have been impossible from the construction of that device to have removed mercury vapor from the lamp. Several ground glass joints were used which was made tight with a mixture of vaseline and bee's wax. A ground glass joint of this kind with this material on it gives off hydrocarbon vapors which are decomposed by the filament when it is lighted and generates considerable quantities of gas and prevents the obtaining of a good vacuum.

There was no treatment of the electrodes, no bombardment of the electrodes, no voltage was applied on the electrodes during the exhaust treatment. I know from my own experience that unless metal plates are heated to a very high temperature by bombardment during the exhaust, the apparatus will not function as a pure electron device in operation.

I discussed yesterday the experiment of the nickel anode tube in which the object was to give the tube as good an exhaust as we knew how or give all the exhaust treatment that we give the tubes that are exhausted most carefully, leaving out only one factor, and that is leaving out the bombardment of the anode during the exhaust for the purpose of heating it and denuding it of gas and I stated that the results showed that the treatment was entirely inadequate. Merely heating the bulb with the electrodes in it does not suffice to free the electrodes sufficiently from gas to allow the proper operation of the tube.

Q. 221. No matter how hot you heat it?

A. Up to any temperature that the glass will stand. If you could heat to a bright white heat by external heating you might be able to——

By The Court:

Q. 222. What temperature would that be?

A. Red heat in an ordinary room begins about 700 degrees Centigrade. In a very dark room you can see at night, with the eyes well rested, you can see it at five or six hundred degrees, but ordinarily you first begin to notice red heat on small bodies in the vacuum at about 700 degrees, and eight or nine hundred degrees would be a fairly bright red heat.

I did not finish what I was going to say. If you could heat to a bright white heat probably you would get the gas out sufficiently well, but the glass will not ordinarily stand over 360 to 400 degrees. Four hundred degrees is approximately the maximum temperature in heating glass bulbs made of ordinary glass. Only with the very hard glass that we use nowadays, like pyrex glass, can you go about 100 degrees higher. Even with pyrex glass we do not heat over 450 degrees.

By Mr. Lunt:

Q. 223. What is your opinion as to the adequacy of the heating means if there was any that was used by these witnesses?

A. There was no way of telling what kind of heat treatment these bulbs received. There was no measure of temperature, or if any attempt was made to measure the temperature it would not have meant anything, because the bulb was not in an oven which would have reached a definite temperature. The bulb was placed above a ring burner, a Bunsen burner in the form of a circle which was placed below the tube and above the tube was a rather flat cone made out of asbestos. Probably the lower part of the bulb was quite hot and the upper part or the sides may have been very much lower temperature. If a thermometer had been placed by the side of the bulb there is no way of knowing whether the thermometer and the bulb were at the same temperature.

Q. 224. Excuse my interruption. Now, will you go on with your answer?

A. I think I had finished my answer.

Q. 225. I do not think you gave me your opinion as to what kind of a vacuum would have been secured, and whether the tube operated with a pure electron discharge?

A. I think an audion made in the way that is described in these depositions would not operate with a pure electron discharge but would operate about the way most audions did operate at that time.

Q. 226. Is there anything else that you found in these depositions or any of them which would alter the opinion you have expressed?

A. No.

Q. 227. Would the method of obtaining the vacuum as set forth in the Lamont and Mrs. Beck's depositions, if used in a device containing a thoriated tungsten filament as set forth in the second, third and fourth of the patents in suit, would it have been sufficient to obtain the degree of vacuum and freedom from deleterious gases characteristic of the devices of those patents, as set forth in those patents?

A. No. The quality and degree of vacuum would not have been nearly sufficient to enable the beneficial results of the use of the thoriated filament to have been obtained.

Q. 228. What are the reasons which you had in mind in giving the last answer?

A. The fact that the electrodes are not sufficiently freed from gas to enable the device to operate in such a manner as to retain during operation the film of thorium on the surface of the thoriated filament. Furthermore, I believe that the bulbs would not have been sufficiently freed from water vapor to have permitted the operation as thoriated filament.

Q. 229. Would the mercury vapor which I understood you to say would inevitably have been present in that bulb, would that have had any effect?

A. That would have prevented the operation of the filaments giving the characteristic emission of the thoriated filament after properly activated at voltages materially above the ionizing voltage, because the mercury ions and the ions of other gases would bombard the surface of the cathode and would knock off the thorium. That is, a thoriated filament which has the high electron emission because of the monatomic film of thorium on the surface is extremely sensitive to positive ion bombardment. It is only a layer of one atom thick which is about one one-hundred millionth of an inch thick. A very minute amount of positive ion bombardment at voltages of say fifty volts will rip off or disintegrate this film and destroy it.

So that the degree of vacuum must be so high that that can not happen and the degree of vacuum in these tubes could not have been sufficiently high for that purpose.

Q. 230. Is it or is it not your opinion that ionization must have been inevitably present at voltages above the ionization voltage in these DeForest tubes?

A. There would have been some ionization just above the ionization voltage, and it would increase rapidly, as the voltage was raised above that.

Q. 231. What difference in operation do you understand there would have been in these DeForest bulbs exhausted by Lamont and Mrs. Beck, as compared with the DeForest bulbs about which you have testified, I mean the DeForest bulbs of 1912?

A. I think they would be like most of the DeForest bulbs of that time. They may possibly have been heated a little hotter than some of the DeForest bulbs were by the Bunsen burner flame, but I do not think there is any real reason to believe so. I forgot to mention among other factors that would have prevented the obtaining of a good vacuum in those devices, the fact that sulphuric acid was used as a drying agent. Sulphuric acid, so far as I know, has never been used in any kind of apparatus for getting good vacuum in modern days. In fact, I have never heard of a case before where sulphuric acid was used as a drying agent. Sulphuric acid is a liquid which boils at a moderate temperature and has a very high relatively high vapor pressure, giving off, sulphur trioxide vapors, which would be a very high hydroscopic, and would probably condense to some extent over the inside surface of the bulb. It is stated in Mr. Lamont's deposition that phosphorus pentoxide was used and sulphuric acid, so that there is no way of telling when one was used and when the other was used. The photograph shows a liquid in the bulb below the lamp, and Mrs. Beck refers to this as the acid bulb, indicating that when she used it, at any rate it contained sulphuric acid. An oxygen-containing substance like sulphuric acid is very bad naturally to use with a thoriated filament. That is, if it is desired to get the high emission which can be obtained from a thoriated filament, a gas such as sulphur trioxide would spoil the surface of the filament. Even phosphorus pentoxide I found destroys the activity, that is, the vapors of the phosphorus pentoxide at room temperature destroys the activity of the thoriated filament.

Q. 232. Now, I would like to direct your attention to the pump used by Lamont and Mrs. Beck, or either of them, and will ask you to explain later, briefly, very briefly, the operation of the pump and whether you find any significance in the fact, which I believe you have not mentioned, although I think it is referred to in the depositions, and I wish you would correct me if it is not the fact that a charge of thirty cents was made for the evacuation of each DeForest bulb?

A. I do not remember that Mrs. Beck states definitely the length of time in which the bulbs were exhausted. Mr. Lamont says in one place that the exhaust was continued for from one hour to two and a half hours. Mr. Lamont speaks of using the automatic lift for the mercury; as the mercury was returned after flowing through the pump, it was returned from the bottom of the pump back to the reservoir (which is referred to as the percolator), by an automatic pump. But Mrs. Beck stated that that pump was not used, I think, until 1913 or 1914, and that before that the mercury was returned by hand in containers that weighed sixteen pounds. That is, periodically, the mercury would have to be lifted from the reservoir at the bottom and poured back into the reservoir at the top. It seems to me very obvious that nobody could afford in a commercial laboratory to spend two and a half hours exhausting a single lamp by a process that required continual attention; lifting the mercury at frequent intervals from one reservoir to another, and watching the operation for two and a half hours, for thirty cents. The thirty cents to me suggests that the exhaust treatment given was of the very simplest sort, and that it could be done without giving very serious attention or attention for any long time.

Q. 233. If Mrs. Beck has testified in effect that the vacuum secured in these DeForest tubes was as good as an X-ray tube vacuum, what inference would you draw from that?

A. Of course that——

Mr. Darby: Pardon me. Are you construing the testimony, Mr. Lunt, or will you refer to the portion of the testimony where Mrs. Beck says that?

Q. 234. I will ask the witness if he can refer to the place in the testimony.

A. I do not know that I can lay my hand right on it. I remember Mr. Lamont refers to the pump, that I think he said he knew the pump gave a good vacuum, because they used it for a very satisfactory exhaustion of X-ray tubes. I think it is in Mr. Lamont's examination where there is reference to the X-ray tube.

Q. 235. Never mind looking up that reference, please. If it be a fact that the vacuum was as good as that in an ordinary X-ray tube, what would be your opinion then as to the degree of vacuum?

Mr. Darby: May I have that read?

(Question repeated as recorded.)

A. The X-ray tube being a gas device requires for its operation a pressure far above that which will be sufficient to prevent the operation of an audion as a pure electron device; so that the fact that the exhausting system was sufficiently good for an X-ray tube, does not prove that it was good enough for the exhaustion of a thermionic device operating as a pure electron discharge.

Q. 236. I now wish to draw your attention to the second, third and fourth patents in suit. In these patents, as I understand, there are set forth certain materials which act to secure and maintain the vacuum. I will now ask you if in the following list of materials which I referred to in various places in the prior art, you find any material, which, according to your experience, would be capable of performing, to a sufficient extent, the functions of the materials referred to in the last three patents in suit. This list is as follows: Phosphorus; arsenic; sulphur; iodine; spongy platinum; mercury vapor; iodine vapor; ammonium; cuprous chloride; mercury amalgam; tungsten; hexachloride. For your convenience, I hand you a paper in which these substances are listed.

A. No one of these substances would produce or would help to produce the conditions that are needed for the proper operation of a thoriated tungsten filament as a thoriated emitter.

Q. 237. Will you very briefly give your reasons, as to each substance?

A. Most of these substances have far too high a vapor pressure. Iodine, for example, mercury vapor; iodine vapor, have relatively high vapor pressures. Sulphur has a very material vapor pressure.

Yellow phosphorus has a relatively very high vapor pressure, but red phosphorus has no appreciable vapor pressure. Phosphorus and arsenic, and in fact sulphur, iodine and of course iodine vapor and tungsten hexachloride vapors would react chemically with the filament and injure it, and tend to destroy the monatomic filament of thorium on its surface.

Mercury vapor obtained either from mercury itself or from mercury amalgams would produce no beneficial action and in so far as the vapor is present it results in positive ionization, it would cause a destruction of the film as a result of positive ion bombardment.

The same is true of each of the other substances which give off vapor in sufficient quantity to give ionization at the higher voltages. Ammonium cuprous chloride would probably be decomposed and give ammonia and nitrogen and hydrogen which would produce no beneficial result but would be distinctively harmful by causing positive ion bombardment. The whole character of these substances is very different from those that are used in the three patents that you have mentioned.

Q. 238. I think you referred to a film in the answer you have just given. What film did you mean?

A. The film of thorium atoms on the surface of the thoriated filament when operating with a high electron emission that is described in the last three patents.

Q. 239. What can you say as to the degree of effectiveness of vaporized tungsten in this same connection, that is, as a vacuum obtaining and maintaining material in connection with the devices of the last three patents in suit?

A. The act of vaporizing tungsten in a bulb, especially when the bulb is cool, greatly improves the vacuum, in that it removes certain gases. That is, the tungsten vapor combines with many different gases. At room temperature it does not combine with hydrogen but it does combine with nitrogen, oxygen, carbon-monoxide, carbon dioxide, and those are gases that are likely to be present in lamp bulbs. However, the fact that it does not remove hydrogen is a disadvantage even of the process in which tungsten is vaporized. If the bulb is cooled in liquid air while the tungsten is vaporized, hydrogen is to a very large extent removed and probably becomes covered up by the deposit of tungsten on the bulb, so that if a heavy deposit of tungsten is formed on the bulb, especially if the bulb is cooled in liquid air during the process, then the bulb can be removed from the liquid air and the vacuum will stay good provided no more gas is evolved from the electrodes, but after the deposit of tungsten is once formed on the surface of the bulb, if any more gas is evolved, as for example from the electrodes, or from a surface of glass that has not been thoroughly covered up by tungsten, the tungsten film is ineffective, almost completely ineffective in removing or combining with such gases.

That is, a deposit of tungsten does not give any keeping action; it is not a surface which will take up gases that may be evolved from electrodes or water vapor that is evolved from the surface of the glass.

That is quite different from the alkali metal which is used in the third patent, and the magnesium or calcium films used in the fourth patent. Those reagents are extremely effective in giving a keeper action, that is, maintaining good vacuum conditions even if gases are evolved from the electrodes or escape from the glass during the operation of the device.

Q. 240. In the testimony you have given I think you have referred to the DeForest audion as being sluggish. What were the facts as to that as they may have developed?

A. In January and February, 1913, when I was told that the DeForest audion was sluggish, I attributed it to the fact that positive ionization so obviously played an important role in the operation of the device. Later, I think it was in April and it may have been in May, when I visited the laboratory of John Hayes Hammond, Jr., at Gloucester, Massachusetts, and talked with Mr. Hammond and also with Professor Pierce of Harvard University who was there at the time, I realized that the sluggishness that had been referred to could have been amply accounted for by the fact that a grid had apparently always been used by these men.

Q. 241. Do you mean a grid?

A. I mean a condenser had apparently always been used by these men in series with the grid and there was no grid leak. I say that would be a sufficient cause for the alleged sluggishness because the condenser would become charged and the charge of condenser would leak off slowly. That is, the condenser would retain a certain charge although there was positive ionization to gradually neutralize the charge and this would not take place instantaneously, so that a certain time was required to discharge the grid after a signal had been received.

I did not investigate the question as to whether there was any other source of sluggishness. As far as I know the audion may also have been sluggish even if the grid condenser had been eliminated but I have no proof of that.

Q. 242. We will come now to another matter. You have spoken, I believe, of some disclosure that you made to Dr. Coolidge in December, 1912, and I think in that connection you referred to or read from your notebook. Will you refer to that notebook and particularly to that page, and I think it is page 157 of notebook 413, and if you find there a sketch of a plan for an X-ray tube, will you state whether you were able to make this function as an X-ray tube or a device like it?

A. I never attempted to make the device function as an X-ray tube and I know very well now from the ideas that I had at that time I would not have succeeded in making an X-ray tube even if I had built a device as illustrated in the picture.

When Coolidge did use the hot cathode to construct an X-ray tube, following my suggestion to him on December 10th, he did a great many things and things that were essential, which I had no idea of on that date.

My experience up to this time with electrodes free from gas had been entirely by the passage of current through the anodes themselves, for I realized that plate-shaped or massive metal electrodes gave off large quantities of gas and that it would be a very difficult matter, if not impossible, to remove the gases sufficiently well from such electrodes.

I did not attempt to solve that problem myself. I by-passed it and went around it by using anodes through which I could pass current, anodes in the form of filaments, because I felt that the other problem was one that was very difficult and I knew that Coolidge had been working along such lines and as to whether or not it would be possible to get massive electrodes sufficiently free from gas was a proposition that he was very much better prepared to work on than I was.

Q. 243. I would now like to direct your attention to the sixth paragraph of your answer to Q. 65, in which you make some reference to the fact that the current was limited by space charge. What was the state of the vacuum in the tube about which you were testifying?

A. At that time the vacuum was extremely high and the discharge was a pure electron discharge in which the current was limited by electron space charge independently of ionization. The ionization was not sufficient to appreciably affect the electron space charge. That same tube in the beginning had shown a relatively poor vacuum, but the vacuum had improved by the treatment that it was subjected to.

Q. 244. Will you now refer to your answer to Q. 216? You there stated that you used all of the knowledge of the year 1920 or thereabouts to get a good vacuum in the tube. Did you endeavor to deprive or denude the anode of gas? I think you have referred to this matter already in one of your previous answers, but I do not know whether it has been made quite clear.

A. I exhausted this tube, using the best methods of exhaust with the exception of the treatment of the anode by bombardment. The anode was only heated by the fact that the bulb was in an oven and the fact that the filament was lighted for a short time. There was no voltage applied to the anode and therefore the anode was not bombarded. That was deliberately and purposely done in order to see what would be the result of omitting this one factor in the preparation of the tube, that is, omitting the bombardment of the electrode by electrons and the resulting heating of the electrode.

Q. 245. I will draw your attention to the answer which you gave to Q. 116, page 1187 of the record, which you gave yesterday, and ask you in what sense you referred to Exhibit 105, tungsten wire audion No. 2, as "the first tube that was made which involved the use of an anode which could be heated to very high temperature to free it from gas"?

A. I meant to say that this was the first audion and not tube. I meant a tube of that character, a three-electrode tube of the audion type which had provision for heating the anode by passing the current through it. You will remember that a few weeks before that I had made an audion type of tube in which the electrons were in the form of plates and could not be heated by passing current through it.

Mr. Lunt: If your Honor please, I now have here the White notebook and the test record about which I interrogated this witness the other day and I would like to have them marked for identification. It was not done at that time.

The Court: Let them be marked. You do not want to put them in evidence. You will prove them by Mr. White.

Mr. Lunt: Yes.

The Court: Very well.

(Received and marked "Plaintiff's Exhibits F and G for Identification," respectively.)

Mr. Lunt: I am through with the direct examination.

Mr. Haight: May we ask your Honor's indulgence, in view of the fact that the labor in this case has been divided in the way I indicated, that Mr. Richmond and Mr. Darby, both be permitted to cross-examine in the respective fields with which they are familiar.

The Court: Yes.

By The Court:

Q. 246. May I find out from this witness the difference between a tube and an audion? You said that this Exhibit 105 or audion No. 2 was an audion and not a tube.

A. A tube is used as a general term to describe any kind of a device other than a lamp with high vacuum. We came——

Q. 247. And an audion is what?

A. An audion is a kind of tube, a vacuum tube. A Fleming valve and an audion and an X-ray tube are all spoken of as vacuum tubes. An audion is a particular kind of vacuum tube.

Mr. Davis: Three-electrode tube. The witness was distinguishing, I think, between a three-electrode tube and two-electrode tube.

The Court: I thought he denied it being a tube and said it was an audion.

The Witness: I said when I referred to it as a tube, I did not have in mind that this, for example, was the first tube in which I had heated the anode, because I had previously made in August, and November and December, I had made many tubes in which the anode had been heated but they were not audions.

The Court: Very well.

Mr. Davis: They were two-electrode tubes.

THE COURT: I get it, but this was the first——

THE WITNESS: Audion that I made.

THE COURT: The first three-electrode tube?

THE WITNESS: Yes.

THE COURT: I just missed that.

CROSS-EXAMINATION.

By MR. RICHMOND:

XQ. 248. I understood you to say that for tubes with hairpin filaments, you expected conformity to the 3/2 power law within something like one or two per cent.; is that correct?

A. I was discussing, I think, the effect of the initial velocities of electrons, and I think I had reference to the accuracy with which that factor would cause deviations in the 3/2 power law, and I may say I had in mind relatively high voltages, because at very low voltages the deviation became progressively greater.

XQ. 249. Would you consider that such a tube was "substantially affected by positive ionization," if the departure was more than one or two per cent., as compared with what it would be for a perfect vacuum?

A. I would not attach much importance to a few per cent. deviations.

XQ. 250. I want to get an idea of "substantially unaffected by positive ionization," as that expression has been used so much. In such a tube, what percentage of departure would be permissible from absolutely unaffected by positive ionization, and still come within the range of "substantially unaffected by positive ionization"?

MR. LUNT: If your Honor please, I think I must object to that. That calls for really an interpretation of the patent and the claims, which I take is for the Court.

THE COURT: Is not that in cross-examination?

My recollection is that the witness said that his first calculation was 1.7. Now, then, whether he is comparing any calculations or variations from infraction of the rule, I do not recall. Is this directed to that?

MR. RICHMOND: It was not directed to that particular example, but more than once he has used that particular expression, referring to his own work "substantially unaffected by positive ionization." For example——

THE COURT: I think that question is permissible, and I overrule the objection.

A. I do not think I can in general define what I mean by "substantially free from ionization" in terms of actual percentages. I think it is just the ordinary common sense meaning of the word "substantially." There is no definite demarcation between a thing that is substantial and a thing that is not substantial. You have got to decide that question for each tube, and take into account all the different factors. I mean nothing more by the word "substantially" than I would mean in ordinary usage. It is not a thing that I can express in percentages.

XQ. 251. Cannot you express it in percentages for a particular case, as, for example, for a tube with hairpin filaments?

A. I do not think so. In fact, if you use a particular curve, it would be a question to decide whether the deviations from the 3/2 power law are probably due to ionization or not due to ionization; and in order to decide that, you would have to take into account the fact, for instance, that the deviation would begin above the ionization voltage, and deviation below that would be ionization and would increase in the way that is characteristic of ionization. Now if the effect were too small, there would come a point where it would be so small that you could not be sure that it was due to ionization or whether it was due to something else.

XQ. 252. Then I understand you that any effect that is appreciably due to positive ionization violates the criterion of "being substantially unaffected by positive ionization," does it not?

A. Will you read that? (XQ.252 repeated as recorded.) To my mind "appreciably" is not at all the same as substantially. You may be able to measure an effect, and yet it may not be substantial, because it may not be important. "Substantially" implies the idea of something more than merely measurable or appreciable; but it means that it has substance, that is, that it is material; that it affects the things that we are considering, whereas appreciable means merely measurable.

XQ. 253. I want very much to get a definite idea of its meaning, and I was hoping that you could answer in somewhat the same way that you did in this place that I mentioned, where you suggested one or two per cent. Suppose you consider a modern General Electric type UV-201-A tube, that is a high vacuum tube, is it not, Dr. Langmuir?

A. Yes.

XQ. 254. Now, if that tube had a perfect vacuum it would have a certain characteristic; we understand that no tube has a perfect vacuum, but what percentage of departure in the operating part of its characteristic would be permissible, keeping within that criterion of being "substantially unaffected by positive ionization"?

A. At for example, at 100 volts?

XQ. 255. At the normal working voltage for that tube. I do not know what it is?

A. Well, that brings us back to the consideration of what the tube is used for, and so on, as to whether it is substantial or not; but practically speaking, it seems to me that if the current at say 100 volts is 10 per cent. or so above what it would be if it had a perfect vacuum, there begins to be substantial ionization. However, if the tube were used for purposes in which reproducibility much greater than 10 per cent. were very important, then, I think that you would have to say that a smaller value than 10 per cent. would become substantial, and on the other hand, if you are using the tube for some other purposes, or the tube is designed for other purposes, it might be that a value of more than 10 per cent. would not be a substantial amount. In other words, I think that "substantially" is to be used in the ordinary common sense way, the way that the man in the street uses it practically, and it is not a thing that has a precise, scientific meaning that can be expressed in percentages.

XQ. 256. And unless you have the use for the device very particularly in view, it is quite a meaningless phrase, is it not?

A. Not meaningless, no. I think, as the ordinary use of the word expresses quite a definite idea, but not necessarily a quantitative idea. I mean, not one that can be expressed in definite percentages. It is a relative expression, like most words in the English language. Their meanings are relative, rather than absolute.

XQ. 257. The current values of which you relied in your August, 1912, work, as plotted in the Interference record at page 2091, were limited by space charge, and were "substantially unaffected by positive ionization," were they not?

A. May I see the reference that you refer to? May I have the question read? (Question repeated as recorded.) Within the accuracy of the measurements, I see no evidence from these currents that positive ionization had any measurable effect on the electron space charge.

XQ. 258. But Dr. Langmuir, it seems to me you are now taking a kind of negative position, that you discovered no evidence that positive ionization was present. I thought your position was that you discovered evidence that positive ionization was not substantially present in this case?

A. I did. That is, it was not present in any amount that produced any observable effect. Of course, there was some ionization, but it was not substantial in this case.

XQ. 259. This means then, that these current values were substantially the same as if there had been no gas in the tube?

A. I think so, within the accuracy with which the measures could have been made, or were made, they are the same as if there had been no gas present.

XQ. 260. And the accuracy of measurement was to what percentage?

A. I should say the voltages were not measured, you see. They were determined from the shop line, and the shop line was on the average of about 250 volts. It may have been possibly ten volts less than that, five or more, or ten volts less. But the difference in those voltages was measured directly, let me point that out. If there is an error of ten volts in the upper reading there would have been an error of ten volts in the same direction in the lower reading. The voltage of 200 for instance, was obtained by subtracting the fifty volts, which was measured accurately from the assumed value of 250 volts. If it had been 240 volts for the upper reading, then the lower reading would have been 190, so that the slope would not have been very much affected.

XQ. 261. But aside from this possible inaccuracy in the voltage readings, you do think there could have been any inaccuracy of such order due to the presence of gas?

A. Of what order?

XQ. 262. The same order that you have mentioned for the voltage readings?

A. I do not know whether you refer to the percentage accuracy or the absolute accuracy, or what?

XQ. 263. You suggested ten volts at something like 200 or 250, that would be?

A. That is 4 per cent., say.

XQ. 264. Yes. Could there have been any such departure from the——

A. Yes. The currents were read on a voltmeter and I think the full scale reflection was 150 volts, and the currents were read to a tenth of a volt. I suppose there may have been something like 10 per cent., 5 per cent., to 10 per cent. possibility of error on the lowest current readings; that is, two-tenths of a volt, possibly.

XQ. 265. But I think that departure that you have in view is a possible instrumental one, is it not?

A. In reading the instrument; not an error in the calibration of the instrument, but the currents were very small.

XQ. 266. But now there was some gas in there, and how much——

A. I beg your pardon. One of these readings, I do not remember now, one of these readings was taken on a milliammeter; the other was taken by the voltmeter.

XQ. 267. There was some gas in the tube, we have all agreed that you can never get all of the gas out of the tube?

A. There was about 0.4 of a micron of gas.

XQ. 268. And in so far as these readings were different from what they would have been in a perfect vacuum, what percentage was that?

A. I do not know definitely, except I can form an estimate of it from subsequent experiments that were made.

XQ. 269. Well, we want your estimate.

A. Oh, I think they may have been 10 per cent. higher than they would have been in a perfect vacuum.

XQ. 270. Now, I want to ask you the same question for your three tubes of November, 1912, the ones that went under the names of lamps 3, 6 and 2; what percentage departure could there have been in the readings there from the perfect high vacuum condition, due to the fact that there was a little gas residue?

A. Well, of course, in these measurements there were a good many different readings. In some cases the vacuum was purposely made bad. Now, excluding those, if I may,——

XQ. 271. That is right.

A. Taking those in which the vacuum was made as good as I obtained in these readings, I believe that the effect of positive ionization in those was entirely negligible, probably less than 1 per cent. That is, the currents in a perfect vacuum would not have been more than 1 per cent., probably not as much as a very small fraction of 1 per cent. different from what they were observed to be. I base that on the fact that the method of exhaust treatment used, for example, in those lamps, is a very excellent one, as when I cool the bulb in liquid air, I know from subsequent experience that I would have obtained an extremely high vacuum, so high that ionization would not have had 1 per cent. effect on the count.

XQ. 272. I understood you to say that when you experimented in December, your bulbs were very much the same as in August, referring to the year 1912 for both months, except that you made them very much smaller for convenience in immersing them in liquid air in December; that is correct, is it not?

Mr. Davis: Is it not November? I simply

do not remember any testimony about December.

A. Mr. Davis, it is in the record, the old record.

XQ. 273. My understanding is that the very latter part of November, 1912, you started another experiment?

A. November 21 I started the experiment.

XQ. 274. That was when Sweetser started, was it?

A. Yes.

XQ. 275. And it ran over into December?

A. Yes.

XQ. 276. And you have relied on data taken in December?

A. I have spoken of them.

XQ. 277. It is that experiment that I am referring to?

A. Yes.

XQ. 278. It is in Exhibit 80 on the motions?

A. The experiment 317, Sweetser's experiment 317.

XQ. 279. Then, this reduction in size of the bulb ~~in~~ that experiment of the latter part of November and the month of December, 1912, as compared with August, 1912—I say this reduction in the size of the bulb was not a material change in the conditions of the experiment, was it, except as it facilitated using liquid air?

A. I do not think it had any appreciable effect. The electrodes were about the same distance apart, if you remember.

XQ. 280. What was that distance?

A. I do not know that I remember now. I think it is given in the notes somewhere, but my recollection is that it was about half an inch.

XQ. 281. I looked rather carefully in the notes and did not find it and that is the reason I asked you.

A. That was our practice at that time in making them up. They were all run on one press.

XQ. 282. Was the exact spacing of the electrodes material?

A. No, it would not have made much difference except in the actual values of the current.

XQ. 283. The further apart they were the less currents——

A. Yes, sir, smaller currents.

XQ. 284. What were the sizes of the bulbs in August and December of 1912?

A. Do you want me to look up the original notes or just from recollection? I remember them approximately.

XQ. 285. Go ahead and give us your memory.

A. I think the August experiments were in a bulb about something like four inches in diameter and the December experiments were in bulbs about an inch and a half or an inch and three-quarters in diameter, a little cylindrical tube.

XQ. 286. In both cases the bulbs were cylindrical?

A. I think so. I know they were in December and I am not quite sure whether they were in August or not.

XQ. 287. If you had repeated the August experiment with the December tube, would the current have dropped to the same space charge value when the pressure reached four-tenths of a micron?

A. The same order of magnitude. Certainly not exactly the same value.

XQ. 288. And if you had your filament temperature at 2225 degrees K., would the current have changed from 16 milliamperes to 5 milliamperes as the pressure was reduced?

A. I do not remember whether the diameters of the filaments were the same or not. If the filament had been a little larger in diameter or different in diameter in the two experiments the saturation current would have been different and the space charge current would not have been appreciably different.

XQ. 289. This August, 1912, bulb has not been saved, has it?

A. No.

XQ. 290. What is the last record you have of it?

A. At the end of the experiment 291.

XQ. 291. That ended in what month?

A. May I see the notes? I have the notes on experiment 317.

XQ. 292. Let me just defer that question. There was nothing important——

A. I think roughly that the experiment lasted until the first week in September, thereabouts.

XQ. 293. That is quite sufficient for my purpose. And that is the last record of the bulb that was used in that experiment so far as you know?

A. As far as I know the bulb may exist. Mr. Sweetser has kept most of the bulbs that he used in different experiments. Of course, a good many have been broken. They have not been very carefully kept.

XQ. 294. Have you made any search for it?

A. No.

XQ. 295. Quite indifferent as to whether it exists or not?

A. Yes.

XQ. 296. There was no particular reason for saving it, was there?

A. No. We obtained the information we wished with it.

XQ. 297. And the particular dimensions and appearance of the bulb which might have been learned by inspecting it or measuring it would be quite immaterial you think?

A. Practically so. We can find the exact shape of the bulb from the record that is made of the lampmaker's number, that is, the mould number was recorded by Mr. Sweetser and that bulb can be duplicated at any time.

XQ. 298. You did save audion No. 2 that was made in 1913, did you not?

A. Not deliberately. I do not think we did deliberately. I certainly had nothing to do with it. If it was kept it was simply because it happened to be kept. We keep some of our tubes and others we do not.

XQ. 299. Aside from the distance between the hairpin filaments in these bulbs of August, 1912, and December, 1912, what was the spacing between the two legs of each filament?

A. Roughly about half an inch or five-eights of an inch at the point of maximum separation.

XQ. 300. And a little variation in this dimension one way or the other would not have materially affected the results which you have testified to, would it?

A. No.

XQ. 301. What was the relative area of the filament and the lead-in wire for the bulb of August, 1912?

A. From the notes I would be able to tell exactly what the area of the filament was because we know the length and the diameter and I can estimate approximately the area of the lead-in wire. But I cannot tell you what the relation was unless I remember the diameter and length of the filament. I think it was probably about a five mil. filament and I think the total length is about 3½ inches.

XQ. 302. For the filament?

A. Yes.

XQ. 303. And what were the dimensions for the lead-in wires?

A. I think in all that work we used platinum lead-in wires, probably about a twenty mil. wire and the part inside of the bulb would be about ¾ of an inch for each lead, maybe ⅝ of an inch. In regard to the diameter of the filament I know that can be found in the notes of Experiment 291. So that although—

XQ. 304. I find I have it noted here. According to my notes it is 4.99 mil. tungsten wire. That seems reasonable?

A. Yes.

XQ. 305. I am sure then that it is in the notes. What was the diameter and length of the filament for the tubes of November, 1912, that is, that go by the name of lamps 3, 6 and 2?

A. The filaments were in length and diameter practically the same as those of 120 volts, 40 watt lamps. There were six loops, I do not remember the exact diameter, although I can calculate it. Roughly, the diameter was about 1½ mils. and the length about twenty or twenty-two inches for each filament before the middle section was burned out.

XQ. 306. And there were four lead-in wires each of what length and diameter?

A. I do not know definitely. Probably normal length of leads at that time. They were not factory made lamps. They were laboratory made lamps.

XQ. 307. But that length was what, the length of those leads was how much?

A. Probably about half an inch, each of those four leads inside of the bulb, perhaps 10 mils. in diameter.

XQ. 308. Suppose the distance between the filaments had been changed in the August, 1912, tube, suppose it had been doubled, for instance, would this have changed the gas pressure at which the current would suddenly have gone down in value?

A. A little, but not very much, though.

XQ. 309. In which way would the change have been?

A. The greater the distance in general the more ionization there would have been, so that I should think the lower the pressure at which the effect would take place, but it would not vary anywhere near as much if the anode were in the form of a plate. The distance would not be so important, because the electrons do not move in a straight line, between the cathode and anode, but they form very curved paths and circulate around the anode for relatively long distances before they are finally able to strike it.

XQ. 310. And would this same change have changed the value of the current at its lower value?

A. Which change, the change in gas pressure?

XQ. 311. Spacing the filaments further apart?

A. It would have decreased the space charge current slightly. Again, not as much as you would have expected from the space charge equations which applied to parallel plates in series.

XQ. 312. Referring to a time before August, 1912, you have said with some emphasis that you introduced a method of hunting for the cause of a certain effect by exaggerating various possible causes and noting whether any one of them gave the effect in an exaggerated degree. Do you mean that this general method was original with you?

A. No, I think I stated very definitely that it was not original with me but it was one that I used perhaps a larger percentage of the time than most people around the laboratory and probably elsewhere.

XQ. 313. Was it by this method that you arrived at the crucial results of August and November, 1912?

A. The experiments in August were made in carrying out that idea, that is, I was deliberately putting gases into lamps to much higher pressures than they ordinarily existed in lamps for the purpose of studying these fundamental factors in the way as I have described, and it was in the course of those experiments that I obtained the results that I testified about. In November, on November 19th, the object of starting the experiment was not an application of that method of working, but in the course of the experiment I did that very thing, that is, as soon as I had produced a good vacuum I proceeded to get a better understanding of the phenomenon that I had just observed by deliberately spoiling the vacuum in two ways, by heating the bulb and by applying high voltages.

XQ. 314. Was the idea of a vacuum oven original with you?

A. Yes, I think so. I have a patent on it. A vacuum oven for the purpose of exhausting bulbs. People may have heated some objects in an oven but I do not know about that. I mean long prior to my work we had a vacuum furnace, an Arsem furnace. That was not for the purpose of heating bulbs, but the purpose of a vacuum in such a vacuum furnace is an entirely different one from the vacuum oven that I made. The vacuum in the oven that I made was not for the purpose of evacuating the outside of the bulb, for example, or getting gases out from the outside of the bulb which is the purpose more or less analogous used in the Arsem furnace, but it was to take away the atmospheric pressure from the bulb so that the bulb could be heated to a higher temperature without collapsing.

XQ. 315. Did you use this vacuum oven on the bulb that you experimented with in August, 1912?

A. We used the oven, but I do not know that we used the vacuum on the outside. I think not. We only baked out that bulb to about 350 degrees, so that it would not have been necessary to use vacuum outside of the bulb at that temperature.

XQ. 316. Nor did you use it for the lamps, 3, 6 and 2 in November, 1912?

A. No, we did not use it then.

XQ. 317. You explained about the use of the radiometer as a vacuum measuring device before August, 1912. Did you use this to measure the vacua in the tubes of August and November, 1912?

A. No.

XQ. 318. You told us about the hot wave manometer that was developed in your laboratory before 1912. Did you use this to measure the vacuum in the tubes of August and November, 1912?

A. No.

XQ. 319. How about the elastic quartz fiber gauge that was developed by you or in your laboratory before the middle of 1912; was that used on these tubes?

A. No.

XQ. 320. And the molecular gauge that had the aluminum disc, was that used on any of these bulbs?

A. No.

XQ. 321. Tungsten lamps were satisfactorily made before you entered upon your study of offsetting, were they not?

A. Squirted filament tungsten lamps were on the market. They were not as good as they were later by any means.

XQ. 322. I understand that the criterion for the presence of the invention on which you relied in August, 1912, is the one that has sometimes been called earmark No. 3. Is this a correct statement of it? Assuming a constant fixed voltage across the tube somewhat greater than the ionization voltage and below the saturation voltage, the current decreases as the vacuum increases, but this decrease slows down and finally stops altogether giving a final definite useful current through the tube, which current is not decreased by further increase of vacuum. Is that a correct statement of earmark No. 3 and is that the criterion upon which you relied to determine the presence of the invention in August, 1912?

A. I do not remember this criterion as whether it is No. 3 or No. 2 or what number it may be, but the statement I think is correct, that is, the current at voltages sufficiently far above the ionizing voltage and below saturation decreases as the vacuum improves and finally reaches or tends to reach a limiting value which does not change as the vacuum gets still better.

XQ. 323. And that is the criterion that you relied on to show that you had a pure electron discharge substantially unaffected by ionization in August, 1912?

A. Oh, not entirely, no. The way that I know that I had a substantially pure electron discharge in August, 1912, is first, that there was a discontinuous break from the value corresponding to saturation, which at the higher filament temperature was about 17 milliamperes, there was a break from 17 milliamperes down to 5 or 4½. That break was not due to the change in the electron emission of the filament. It was due to the fact that a new factor came in which limited the current and I know now that that fact is space charge, electron space charge, which limited that current.

The fact that the pressure continued to decrease over quite a perceptible range without any material further change in current is earmark No. 3, if you wish to call it that. That is another fact that indicates that the discharge was practically a pure electron discharge.

A third fact is that the two measurements at different temperatures a similar break or decrease in current occurs at about the same pressure in both cases but in one case it comes down to 4½ milliamperes at 250 volts and the next time it comes down to about 3 milliamperes at 200 volts, and those two values of 3 and 4½ are close to what you would expect from the 3/2 power law, as close as measurements are accurate to.

Then there is another fact, and that is, at the higher current of 17 milliamperes there was a pronounced purple glow and that that disappeared when the current decreased abruptly to the value of 5 milliamperes or 5½, so that the absence of the glow is another factor which helps to indicate that the character of the discharge had been entirely changed and that the currents were now limited by space charge, electron space charge.

Now, the reason that I attached quite a good deal of importance in this case to the blue glow or the purple glow was that the currents were large; that is, 5 milliamperes at 250 volts represents a good deal of energy and the absence of blue glow under these conditions is a pretty good indication that there is not very much ionization.

By itself that is of no importance, but that taken in conjunction with our later observations that under those conditions when blue glow does not occur with 5 milliamperes at 250 volts, there is not enough ionization to modify space charge to any great extent, is just another indication that we are dealing with——

XQ. 324. You mean that there was blue glow——

A. Purple glow in this case.

XQ. 325. Yes, when the current was at 17 milliamperes?

A. Yes.

XQ. 326. But that that disappeared when the current dropped to 5 or 4½ milliamperes?

A. Yes.

XQ. 327. Have you ever mentioned that blue glow before in your testimony?

A. No, I think not.

XQ. 328. Is it mentioned in Sweetser's notes?

A. Yes.

XQ. 329. I wish you would show me where?

A. I called attention to that fact——

XQ. 330. I understood you to say that in 1912 Dr. Coolidge had the remarkable result that in the old-style X-ray tube with the discharge going, and his electrodes white hot, the discharge stopped suddenly and abruptly; did I understand that correctly?

A. That was what we thought we saw.

XQ. 331. Please tell me what you did see in the light of your present knowledge?

A. In the old-fashioned X-ray tube the electrons are emitted from the cathode as the result of positive ion bombardment. That positive ion bombardment not only knocks electrons out of the cathode, but it also causes the heating of the cathode. At the higher gas pressures or with cathodes which are not very thoroughly freed from gas, there is not a great deal of heating at the cathode; but when Coolidge used a tungsten plate as a cathode (I think he had it a little distance back in the side arm so as to get a focusing action on the target), for some reason, I do not know just why, the positive ion bombardment became very much more intense in proportion to the electron current, so that the heating of the cathode became more and more marked until finally the cathode became about as hot as the anode, and both electrodes were a bright white heat. Now, during that process the clean-up of gases was going on all the time. That is, with the high voltage discharge, gases are disappearing continually, and finally the pressure became so low that the supply of positive ions on the cathode was no longer sufficient to supply the requisite number of electrons to maintain the discharge.

Now, at that time, just before this device stopped, the cathode was a bright white heat, and both Coolidge and I thought that if it was ever going to emit electrons it surely must be emitting electrons at that time as a thermionic cathode. Verv likely it was emitting electrons, but suppose it was emitting electrons, it is very obvious that it could not continue to emit electrons after the vacuum got too good, because there was then no source of energy at the cathode: if the supply of positive ions disappears there is no longer any mechanism for getting the cathode hot. The emission of electrons does not keep it hot. Only positive ionization keeps it hot, and the thing that we did not realize at that time was that, of course, as soon as the gas pressure falls below a certain point, no matter how many electrons a cathode might emit at the temperature that it had just been at, it will be found to cool off as soon as the supply of positive ions disappears. Since it was only the middle part of that cathode which was heated, and the heat was being conducted out of that part very rapidly, the very instant the supply of positive ions disappeared, or became too small, the hot spot in the center of the cathode would cool off, and as soon as it cooled off below the point where it would stop emitting enough electrons, it would still be at a white heat, 2000 degrees or thereabouts. The supply of electrons would stop and then the entire discharge would stop, and of course the whole thing would cool off; and the rapidity with which it would cool off and the discharge was stopped, was so great that it could not be followed by the eye. So that we could not see by the eye what the exact sequence of events was actually, before the tube stopped. The cathode must already have cooled off, probably cooled off considerably before the discharge actually stopped; but the difference in time was so small (probably a very small fraction of a second it was actually) that the tube gave the appearance of ceasing to function while the electrode was white hot.

What really happened was that the supply of positive ions disappeared. The cathode was no longer maintained at the high temperature. It fell to a temperature at which it could no longer emit electrons, and the whole device ceased to function.

But at that time neither Coolidge nor I, nor did Professor Richardson, on October 12, 1913, have any suggestion as to how that experiment could indicate anything other than the conclusion that the electron emission in a very high vacuum from tungsten must disappear. It looked to us all as though when the vacuum became too good the electron emission action stopped. We can see that what really stopped was that the positive ionization stopped, and the source of heat at the cathode disappeared, and therefore the tube cooled off and ceased to function.

XQ. 332. I understood on your direct testimony that you said that while the electrodes were a dazzling white heat, the current suddenly stopped?

A. That is the way it appeared; actually the cooling effect probably took place within a fraction of a second before the discharge stopped.

XQ. 333. And if it had stopped actually while they were at a dazzling white heat, that would have been a nut for Richardson to crack, would it not? I mean that——

A. We do not know whether it had stopped simultaneously with it, or a fraction of a second before. I simply told Richardson what I had seen. I mean Richardson and Coolidge and I were all in the same dilemma, all three of us.

XQ. 334. Richardson did not see it himself, did he?

A. I think he saw it when he came to the laboratory in November.

XQ. 335. But he had not seen it when you told him about it in October, 1912?

A. No.

XQ. 336. And you did not tell him then that the current stopped after the cathode cooled off, as you now tell us?

A. Of course not, because I did not know it myself. I do not think he would have known it if he had seen the tube working either.

Mr. Richmond: I think I must object to the answer, your Honor.

The Court: That last part may be stricken out.

XQ. 337. So that the explanation that Richardson failed to make when you told him about it, was that the appearances were deceptive, was it not?

A. No. No, he never said any such thing. I misunderstood the question. Will you read the question? (Question repeated as recorded.) I suppose he failed to make lots of explanations, but all that I remember that he said was that he did not understand how those facts could be explained.

The Court: If I understand the tube at that time, there was no heating of the cathode by the current?

The Witness: No. The cathode was a flat plate about an inch and a quarter in diameter mounted on a stem, and there was no provision for heating it.

XQ. 338. What you told Richardson was that the current stopped while the cathode was at a dazzling white heat, was it not?

A. I think I told him what we had seen. That is the whole setup of the apparatus, and I think I told him quite a good deal about it; I mean, all there was to tell as a matter of fact.

XQ. 339. And this statement was comprehended within what you told him—that the current stopped while the cathode was at a dazzling white heat, just as you have told it to us?

A. As I remember, I told him what I saw. That is, we had the tube operating with both electrodes at a dazzling white heat, and while we were looking at it, it suddenly stopped functioning, and no current could pass through the tube, the electrodes being at a dazzling white heat at the time. Of course they were a dazzling white heat; even after the electrode cooled off, it was still white heat because tungsten will not admit a sufficient number of electrons at say 1900 degrees or say 2000 degrees absolute, there would not be a sufficient temperature to allow the cathode tube to emit electrons and still it would be at a white heat, perhaps not dazzling, but a very bright white heat.

XQ. 340. Referring to Exhibit No. 163 which you produced on your direct examination, this shows the current gradually declining from eighteen milliamperes to sixteen. That was where the blue glow appeared, was it, at that stage (indicating)?

A. I think there was blue glow all during that time. The notes that Mr. Sweetser made on the blue glow were mostly just before and just after the break occurred, that is, he contrasted the condition of the tube before and after the sudden decrease in current.

XQ. 341. And called attention to the blue glow before and the absence of it after, yes?

A. The purple glow, yes.

XQ. 342. Now, can you point that out in the notes (indicating)?

A. It was not in this particular experiment that I refer to. It was on a repetition of that experiment, about a few days later where the same voltages and practically all of the same conditions existed in the tube. The points that I refer to are on pages 1186 and 1187.

XQ. 343. Just point that out for the record.

Mr. Howson: Of the Sweetser notes.

A. About three-fourths of the way down on page

1186, at the time, twenty-three minutes past three, or twenty-five minutes past three, rather, it is stated: "Pronounced purple glow" for a current of seventeen milliamperes.

And then at 3.36, the current was five milliamperes, and it said: "There was no glow," and then at the very top, the first two lines on the next page, 1186: "At 17 milliamperes again there was a 'strong glow,' and at 5 milliamperes, there was 'no glow.'"

I can give you the pressures there, if you wish to know.

XQ. 344. No. That is sufficient for the present. Now, I want to confine attention to the work that is recorded on Exhibit 163, was or was not there blue glow before the sudden drop in current occurred?

A. There was no reference to the notes on that point of blue glow, but I believe there was a blue glow before the break occurred, because the conditions were identical, so far as I can tell. I believe they were identical with those that were recorded at this later date.

XQ. 345. Are you sure that that happened?

A. I do not remember.

XQ. 346. Then, of course, you have no independent recollection as to whether there was blue glow or not?

A. But I know—I remember distinctly seeing the blue glow in the tube.

XQ. 347. But not on this occasion. I mean the occasion——

A. The occasion of the experiment.

XQ. 348. Not on the occasion for which the records are plotted on Exhibit No. 163?

A. No. I do not remember whether there was blue glow or not from my observation at that time.

XQ. 349. A little while ago you enumerated several indications on which you based your conclusion that you had a pure electron discharge "substantially unaffected by positive ionization," in August of 1912. The second of these indications was that the current remained constant after it had dropped to its lower value. Can you show me a single place in Sweetser's notes where constancy of current is recorded?

A. When the current dropped from sixteen down to five, or jumped from seventeen down to five, and back to sixteen, and down to five again, that fact was recorded very carefully by Mr. Sweetser. The pressure there then was about 0.5 micron, and the reading of five was recorded twice at the lower pressure.

XQ. 350. Five milliamperes?

A. Five milliamperes of current, and then the pressure decreased to 0.37 microns, which was about a 25 per cent. decrease in pressure, and the pressure is still recorded as five. In other words, 25 per cent. decrease in pressure caused no appreciable or no measurable change in the current. Practically the same thing happened in Run 2, the pressure changed from 0.54 down to 0.44 and the change in current was from 3.2 milliamperes down to 3.0, which was practically a negligible change, compared with the change that had taken place at a higher pressure. Now, the reading taken at the lowest pressure on Run No. 1 was recorded at 4½ milliamperes, which is less than the value five milliamperes given just before. So it is probably that the current had not quite reached its ultimate limiting value.

The significant thing, I think, however, is that although there was a change of about over 30 per cent., 33 per cent. or so decrease in the pressure, the changes in the current were practically within the limits of reading by the instruments, and were very small relatively to the enormous change that had taken place before that when the current decreased from sixteen milliamperes. Those results in themselves would not, of course, establish the fact that the current was going to stay constant down to zero pressure, and it did not occur to me at that time that this experiment indicated any such thing. As I said, it did not convince me that I could have gotten the discharge in an absolutely perfect vacuum. I did not know at that time that this current would reach the limiting value, but I believe that now, from what I have learned later about the discharge, I believe that it had reached practically its limiting value, certainly within 10 per cent. probably a little less than that.

XQ. 351. But there is no record in Sweetser's notes of two successive readings at these lower values, showing the current to be the same——

A. Yes. I just stated that there was reading of five milliamperes so recorded at two pressures which were 25 per cent. different, three times; in fact, it was recorded three times in succession, five milliamperes. At the time 2.31 is given five milliamperes twice, and then at 3.34, at a 25 per cent. lower pressure again the current is given at five milliamperes, so that three times in succession the current was given at five milliamperes.

XQ. 352. Oh, yes, the first time was when it jumped down to that and then it jumped back up, and the next time was when it jumped down to that again?

A. Yes, and the next one, the pressure is 25 per cent. lower, and it is still five milliamperes.

XQ. 353. And after that the current dropped down to 4½ milliamperes?

A. Yes. I do not believe we were reading those currents any closer than to the nearest half of a milliampere; that is, there may have been an error of a quarter of a milliampere in those currents.

XQ. 354. I understood you to refer to this jump, this sudden decrease of current as a very remarkable phenomenon. That is, as your diagram, Plaintiff's Exhibit 163, shows, with almost no change in pressure the current suddenly jumps from sixteen milliamperes down to five milliamperes, then without any time interval long enough to record, it jumps back again to fifteen milliamperes and then as quickly jumps down again to five milliamperes. When it jumped back to sixteen milliamperes it showed blue glow presumably, did it not?

A. I do not know. Very likely.

XQ. 355. It seems to me it would be likely if it showed at seventeen milliamperes. Is not this kind of thing, flickering blue glow and then no blue glow, just what was familiar in the DeForest audions of the prior art, blinking as they called it?

A. At low voltages around thirty or thirty-five or forty volts such phenomena were common in the DeForest audion due to the changes in gas pressure that had taken place.

XQ. 356. And the DeForest audion had a very different geometry from this August, 1912, tube, did it not?

A. Some of it did. The filament in many of the tubes was pretty much exposed on one side. In some cases the filament and grid was on one side and in that case the geometry was not so very different as it would be in the case where the filament was entirely surrounded by the anodes.

XQ. 357. And you never get this jumping of current from a high value to a low one and back with tubes in which the anode rather completely surrounds the cathode, do you?

A. I do not know whether you would get it under those conditions or not.

XQ. 358. Then you do not know of any experience of getting it with the anode surrounding the cathode, do you?

A. Do you mean now having it periodically changed from one value to another? Yes, I think I have seen it.

XQ. 359. I mean intermittently.

A. Yes, I am pretty sure I saw it in some tubes in which we used mercury vapor.

XQ. 360. Just please describe them a little more in detail.

A. My recollection is not very clear, but I think some of the work that led up to the making of that kenotron containing mercury vapor in the Interference motion——

XQ. 361. I guess that tube was sometimes referred to as the regulator kenotron experiment?

A. Yes, but some of the preliminary experiments made before that, I think we saw intermittent glow.

XQ. 362. And those had cylindrical anodes?

A. Partly. It was a cup-shaped anode.

XQ. 363. A cup-shaped anode?

A. The sides were cylindrical but one end was closed and the filament extended up into this cup-shaped anode.

XQ. 364. So that the enclosure was far from complete in that case?

A. I think it is about as complete as it is in most tubes today. It is not quite.

XQ. 365. I do not mean to set up most tubes of today as my standard of comparison, but I understood that you had worked with cylindrical anodes and axial cathodes in which the anodes were rather long and I had this in mind when I put my question. You would not get such flickering effect in such a tube as that?

A. I do not remember having obtained it with those tubes.

XQ. 366. Do I understand correctly that you have occasionally remarked that charges on the glass walls of a tube have a gridlike action in controlling the current flow. Is that a correct statement of your testimony?

A. Yes, the effects are quite analogous to the action on the grid in many ways.

XQ. 366a. And a variation of the charge on the glass walls may stop the current flow and a variation the other way may permit the current flow to start again, is that right?

A. Under some conditions, yes.

XQ. 367. Referring again to your Plaintiff's Exhibit 163, when the current was at and near the value of seventeen milliamperes it was limited by the number of electrons emitted from the filament, was it?

A. Yes, I think so.

XQ. 368. And at that time there was abundant positive ionization in the tube, was there?

A. Yes.

XQ. 369. And what was the charge on the glass walls at that time, positive or negative?

A. Probably negative. Surely negative.

XQ. 370. Will you please give us your reason?

A. Do you mean the charge or the potential? There is a difference.

XQ. 371. I confess I will have to ask you to explain the difference. I wish you would.

A. I think there was a negative charge on the glass but the potential of the glass was probably above that of the cathode. If you say the potential of the cathode is to be taken as zero then the potential of the glass was positive but the charge on it was negative.

XQ. 372. Do I understand that when you say you think that the charge on the glass was negative even though the potential was positive you mean that the algebraic sum of the positive ions and the electrons on the glass wall was negative?

A. Yes. Potential is not the same as electric charge, but potential results from the distribution of electric charges.

XQ. 373. Yes, I think you made that clear, and you think that at that time the potential was positive relative to the cathode?

A. Slightly so.

XQ. 374. But when the current fell a little later down to 5 milliamperes from the value of 17 milliamperes, the tube was then operating, according to your view, as substantially unaffected by positive ionization and the current was limited by the space charge effect; is that correct?

A. Yes.

XQ. 375. Now, please tell us what modification the device was subjected to, what was done to convert it from one class to the other just in that brief instant of time?

A. Do you mean what took place of its own accord or what we did to it?

XQ. 376. What you did to it first.

A. There were both positive and negative things we did to it. We were applying voltage which was causing ionization of the gas and producing positive ion bombardment of the filament which was disintegrating the surface of the cathode and causing the tungsten vapor to leave the filament which combined with the nitrogen and thereby lowering the pressure. That was one factor that caused the pressure to lower.

The other thing that is very important is that we had previously baked out this bulb and the cathode and the anode to such an extent that this same positive ion bombardment did not cause the evolution of the gas from the glass and the electrodes and the bombardment of the anodes did not cause any evolution of the gas. Unless we had done those things I do not think the pressures would have gone down in the tube the way they did. Other gases would have been evolved.

XQ. 377. Now, I will ask you what you did intentionally to convert the tube from a tube operating with abundant positive ionization to one manifesting a pure electron discharge substantially unaffected by positive ionization?

A: I did not plan to make a tube that would operate substantially free from ionization. That was not my intention. We were studying the clean-up of nitrogen at different pressures and with different electron currents; filament temperatures and so on, and I wanted to work at very much lower pressures than we had before so as to see what the laws of the phenomena would follow at low pressures of nitrogen.

We started in with five microns of nitrogen and let the gas clean up, knowing perfectly well that it would clean up because all our work before that had shown that the nitrogen pressures did go down as the discharge passed through the lamp.

So that we knew perfectly well we would lower the pressure from what we started with and the pressure was allowed to go down and we took the readings of the pressure and the current and the filament temperature and we watched what happened, not knowing what was going to happen beforehand. That is what happened.

XQ. 378. What happened was that the current flickered and then took decidedly lower values than it had before?

A. Yes.

XQ. 379. And thereupon you ceased taking further current readings, did you not?

A. We did not take any below those that are noted in that diagram.

XQ. 380. You did not know at the time or you did not suppose at the time that you had a pure electron discharge substantially unaffected by positive ionization, did you?

A. No, I did not draw that conclusion at that time. I know now, but I did not know it then.

XQ. 381. And the reasons you think you know now are the four reasons you mentioned a little while ago, the fact of the drop in current, the fact as you say, that the current remained constant after the drop, the fact that at two different voltages you can get an approximation to the 3/2 power relation, and the fact that you had purple glow before and did not have it after?

A. And also the fact that since that time I have repeated experiments very much like that one and know what kind of things happen in a device of that character and also I know how good the exhaust treatment was that we had given that lamp in August, and that it was ample, apart from the nitrogen that was there, it was ample to give a pure electron discharge just as soon as the nitrogen pressure was reduced to a certain value.

XQ. 382. You say apart from the nitrogen that was there?

A. I mean up to that time. We put in nitrogen.

XQ. 383. And that nitrogen had not gotten to the outside of the tube at any stage of this experiment, had it?

A. I do not understand that.

XQ. 384. It had not gotten outside of the tube at any stage of the run indicated on this Exhibit 163?

A. No, it was converted into a very stable compound of nitrogen which deposited on the bulb in the form of a nitrite of tungsten.

XQ. 385. If it was so stable why was it that the current flickered back and forth here from 17 milliamperes to 5 and then up to 16 again and down to 5 again. What was the reason for that flickering like that? Was it that more gas came out?

A. There were probably two balancing factors, that nitrogen was being cleaned up at a certain rate resulting from positive ion bombardment, and also nitrogen was being evolved by the decomposition of this deposit on the walls and also resulting from positive ion bombardment of the walls.

XQ. 386. Then if nitrogen was being evolved, it seems to me that you did not have an ideal vacuum at all. I should not use the word "ideal," you did not have a practically good vacuum?

A. After the clean-up went beyond a certain point the bombardment of the walls would be very much less, that is, with those lower currents. I do not maintain for a moment that the vacuum there, in view of the fact that we had 3/10 of a micron of nitrogen was as good as we have in the present-day devices, or as good as we had in either of the experiments in November, but it was sufficient to have the currents limited by space charge without being very materially affected by positive ionization.

XQ. 387. You have just said that an additional reason why you were satisfied that you had a pure electron discharge here substantially unaffected by positive ionization is that in later months or years you have done experiments to throw light back on this. What were the additional indications in those later experiments that you did not have in this one?

A. In the later experiments we did not stop at 3/10 of a micron of nitrogen but we kept right on going to much lower pressures. We found that when we did go to these lower pressures, that the conditions did not change appreciably from what they were in the experiments described here.

XQ. 388. And in other respects were the conditions of your later experiments the same as for this one?

A. Substantially the same.

XQ. 389. You never testified about those later experiments?

A. I made the experiments for years on the effects of gases and filaments of different shapes and sizes. I have not testified about them. I have testified about the experiments in December and in the December experiments we did just that thing, we went down to lower pressures than 4/10 of a micron and the currents stayed substantially constant, as we went down below that point. They did not change very much.

XQ. 390. Tell us what those later experiments were that you mention?

A. I have had Mr. Sweetser at different times, particularly about 1920 or thereabouts, work for months with tubes containing two filaments and also tubes containing a filament and a cylinder in which we could put in at different pressures different gases and study the effect of the gases in neutralizing the effects of space charge, so that they have given me a general familiarity with this whole field so that I know from that general experience what would have happened if we had pumped this down much more, that is, the current of 5 milliamperes might be changed to 4½ and possibly might have gone down a few tenths of a milliampere below that but nothing more would have happened even if we had a vacuum one thousand times as good. Most of the effect had taken place in those August experiments.

That is much more nearly true with the bulb as we had it designed at that time, that is, with the two filaments, than it would have been with a cylindrical anode, for the reason that I mentioned before, that with the cylindrical anode the positive ions that were formed had to get back to the cathode, whereas, in this case, the positive ions that are formed, a large percentage of them, perhaps 90 or 95 per cent. go to the walls rather than go to the cathode.

Therefore, they are removed from the region of the discharge much more quickly and are therefore made much less effective, and it is also for that reason that the discontinuity takes place so abruptly. That the break in the curve occurs so definitely at a given pressure is largely the result of the fact that the walls of the tube played a part in removing positive ions and in changing the potential at that moment. That is, at the moment that the current became limited by space charge, the walls became more strongly negatively charged and then remained practically constant in potential from that point on as the pressure was still further lowered.

XQ. 391. And when they became more negatively charged they exerted more of a grid-like action to restrict the flow of current in the tube?

A. Not appreciably when the current once fell to its lower value.

XQ. 392. How do you know?

A. From the experiments that were made. The potential of the glass does not change very much as you go into lower and lower pressures in these cases when the current is limited by space charge.

XQ. 393. You did not know that in August, 1912, did you?

A. No.

XQ. 394. How do you know it now?

A. From the fact that the current follows the 3/2 power law as well as it does in the presence of low pressures of gases in bulbs.

XQ. 395. Just before that break occurred there was almost the same quantity of gas in the tube as just after it occurred, was there not?

A. I think so, substantially.

THE COURT: You are referring to what exhibit?

Mr. Richmond: Thank you, your Honor. I refer to Plaintiff's Exhibit No. 163.

XQ. 396. Then it was not any notable decrease in the quantity of gas in the tube that caused the drop in current, was it?

A. That was the occasion that made it take place at that time. The pressure fell to such a value that the positive ionization was no longer sufficient to break down the electron space charge or neutralize it.

XQ. 397. And just before that occurred the walls were charged to a positive potential relatively to the cathode, you have said, and after it occurred the walls were charged to a negative potential relative to the cathode?

A. To a small positive potential in one case and a small negative potential in the other case.

XQ. 398. And just to the degree that there was that difference you got a grid-like action——

A. There was no grid-like action before that break took place. As I have said before, when there is approximate neutralization of space charge, the potential of the wall has no effect on the current from the cathode because it is shielded by a positive ion layer near the surface of the glass wall. There is a shielding action. Only after you get this break, only after the break at the lower value had taken place did the potential of the wall have any effect on the discharge. Before that it was quite immaterial what the potential was.

XQ. 399. And before that the current was at nearly, if not quite the full emission value of the cathode?

A. Yes.

XQ. 400. And after that it was to a degree at least restricted by the negative wall charge, was it not?

A. The negative wall charge fixed the potential of the walls at practically zero volts.

XQ. 401. I thought you said a moment ago—

A. It may have been half a volt negative with respect to the filament. Very negligible compared with the 250 volts that we had on the tube.

XQ. 402. Would that very slight negative potential suffice to draw the positive ions out of the path of the discharge current as you have indicated?

A. It does not draw them out, they go out of their own accord. They follow in straight lines in the discharge and they will strike the bulb unless the bulb actually repels them. You do not need a large negative potential on the bulb to pull them out. They will go out all right.

XQ. 403. How do you know that the change in the wall charge which you say occurs at the drop in the current as shown on Plaintiff's Exhibit 163, how do you know that that change of wall charge did not cause the drop?

A. I have been working for the last three or four years on discharges in gases from filaments under conditions that have enabled me to study those wall charges with a great deal of detail and I know that when you have currents at those larger pressures, that you have practically complete neutralization of space charge, you have as many positive ions per unit volume as you have electrons.

The potential distribution of the tube at that time is an entirely different one from what you get after that break has taken place. You have what is called a cathode drop. Nearly all of the drop in potential takes place near the surface of the cathode. The electrons are speeded up to high velocity right close to the surface of the cathode and they travel out in a nearly straight line away from that cathode filament and they strike the bulb or the walls which are slightly negatively charged with respect to the gas as a whole, although they may be positively charged with respect to the cathode.

Under those conditions where you have that neutralization of space charge I know that the potential on the walls has no appreciable effect on the distribution of current within the device. I have tried that under the most varied conditions and I have put on the inside of the bulb an electrode which fits the surface of the glass and I placed potentials on those electrodes for the purpose of studying that very thing, and I know that as soon as you have this neutralization of space charge that the potential on the walls or on the electrodes near the walls are quite without effect on the discharge.

But the moment you get down to this other condition where the current is limited by electron space charge then the potential of the walls if it varies, has an enormous effect on current between the cathode and anode.

The whole action of the audion and a lot of the control devices that we are making at present in the presence of gas depends essentially on these effects, which I have studied in great detail, and a few of which I have published.

XQ. 404. And although you are so sure that it could not have been a change in the wall charge, that cut the current down in this case, it is a fact that in such tubes a change in the wall charge frequently does cut the current down to nothing, or almost nothing, just as you have testified?

A. If the pressure is at the point where the break occurs, the wall charge is one of the factors that helps to determine the exact place that that takes place; but I say that when you are on that upper part of the curve, where the current is limited by saturation, the potential on the walls is without effect. Now, the critical region would be affected, to some extent, and is affected in this case, by any balance in the relations between the positive ions going to the walls, and the electrons going to the walls; but that does not affect the point that I emphasize, and that is, that just before the break occurred, the potential on the walls had no effect.

XQ. 405. I think that I can accept that statement readily enough; but I want to know about the effect of the potential on the walls after the break occurs.

A. The potential after the break occurs, the potential on the walls is practically fixed by the initial velocity of the electrons, and the potential from that point on is very close to the same potential as the negative end of the cathode, within a volt or so of the potential of the negative end of the cathode, so that these variations are negligible then, compared with the voltage on the anode.

XQ. 406. And that statement does not apply though, for your November, 1912, work where the current stopped entirely, did it?

A. But that was when I applied voltages of 200 and 250 volts to the glass walls, not due to the changes of one volt or so, and that would occur in cases like that correspondingly. Of course, after the current is limited by space charge, if you then could charge the walls negatively to 200 volts, it would stop the current entirely; but here the potentials are not due to any such external cause as that. They are due to the initial velocities of the electrons, and those potentials due to that cause are very, very much smaller than those that can be applied externally.

XQ. 407. How did you apply those high voltages in connection with the November, 1912, tubes?

A. By surrounding of the bulb with my hand, and taking hold with my other hand of electrodes, the terminals of the shop line, for example, one end of which was say zero volts, the middle at plus 125 volts, and the next one was plus 250 volts. That is, there was 250 volts difference of potential between those terminals, and by touching them in succession with one hand, while I held on the bulb with the other, my body acting as the conductor, I would carry those potentials on to the outside surface of the bulb, and that would induce charges on the inside surface of the bulb, and thereby change the current flowing through the tube.

XQ. 408. And it is only by some such external application of a high voltage, that you can cause the current to stop by wall charges in such tubes, is it?

A. No. If you take the entire bulb and immerse it in liquid air, it may charge up to much higher negative potentials, due to the fact that the charges can not leak off, and under these conditions the discharge is likely to stop. However, when you raise the voltage to a point where it does start again, you get exactly the same current as though you did not have the bulb in liquid air. There is no half way about it. It is either all on or off. There is no controlling action in the sense that you can cause continuous variations of that current.

XQ. 409. There is a change in potential on the walls for a tube such as that of August, 1912, when this jump occurs that is shown in Exhibit No. 163, is there?

A. Oh, yes, the glass becomes slightly more negatively charged, and it goes to a potential slightly negative with respect to cathode. Perhaps one volt or a volt and a half negative, with respect to the negative end of the cathode.

XQ. 410. And was it slightly or substantially positive before that?

A. Well, I have no way of telling just how much. Several volts positive, probably.

XQ. 411. And the total change is those several volts one way, plus the fraction of a volt, I think you mentioned, the other way.

A. Yes.

XQ. 412. Now, how about the change in pressure that occurs at that time; how much is that?

A. Well, the change in current occurs practically instantaneously, and I do not suppose there is any appreciable change in pressure just at that moment while the current is changing.

XQ. 413. Have you ever measured the wall potentials in such a tube as that of August, 1912, when the pressure was at about four microns pressure?

A. Only indirectly. I have not made specific measurements of the potential, but I can draw conclusions as to the potential from the characteristics of the tube.

XQ. 414. How nearly directly? Please indicate how remote you mean by the word "indirectly."

A. Well, I mean that if the current is limited by space charge, and not by saturation, the walls act like a grid, and if the walls are at practically zero potential, they will act like a distant grid at zero potential, not a grid which is right close to the filament, but one that is a long distance from it; whereas, if the walls were at a large negative potential, they would act like a negatively charged grid and stop the current.

Now, the whole behavior of the tubes of this character even with pressures up to four-tenths of a micron, is such as to indicate that the equivalent grid or the action of the glass as a grid, is that of a grid having very close to zero potential, not a grid that has a large negative potential, or a large positive potential.

Furthermore, the theory of the factors which causes the charge on glass, is well understood. That is, I have investigated them in considerable detail, and in gaseous discharges, I have measured the potential of the glass walls by very direct methods, several methods, and from an understanding of those factors that I get, I believe that the charge on the glass under these conditions where we had five milliamperes at 0.4 of a micron would not be materially different from what it would be at lower pressures. That is, a few volts or so, with respect to the negative end of the filament.

XQ. 415. I understood you to say that you thought there was no accident with the tube of August and September, 1912, that required re-pumping. Please look at page marked S-5, for August 30th, and see if there was not such an accident.

A. I do not remember having said—please read the question? (Question repeated as recorded.) I do not remember having said that the bulb was not re-exhausted. As a matter of fact, I do remember having pointed out——

XQ. 416. I may not have indicated that page in Sweetser's notes correctly. The date is right, and it has a 5 on it.

A. I might say that this experiment 291 was started with one lamp, and that lamp was found to leak, so a new lamp was substituted. That was on S-1148, and I have already called attention to that fact, and the exhaust schedule that I describe was of the second of those lamps. Now, all the references that I have made to the experiments described in this experiment 291, have, I believe, been prior to August 29th, and I have not meant to refer to anything that was done after that time. I notice under date August 30th, these are my notes taken and recorded in my own handwriting, I think at the time that Mr. Sweetser was away for a few days for sickness or for some other cause, and I was applying the high voltages from the spark coil to the bulb, and near the top of page 5 of these notes of my own is the record:

> "Punctured glass, repaired with balsam and exhausted."

That exhaust, however, does not mean anything more than the fact that we used the pump to lower the pressure, which is a thing that we did practically every day, as we were doing with all these experiments. That is, we put in nitrogen and allowed the gas to clean up, and before putting in more nitrogen, we would exhaust the residual gas left over from the preceding run, so as not to allow impurities to accumulate.

The Court: Recess until 2.15.

After Recess.

Mr. Davis: If your Honor please, among the exhibits offered by the defendant in the Interference and reoffered in the present case is an exhibit consisting of certain extracts of the testimony of Major Armstrong which was 125 in the Interference and 237 in the present suit. Major Armstrong is here prepared to testify and if this exhibit should go in we would desire to take his testimony. My friend Mr. Darby has decided that he wishes as we all do to shorten the case as much as possible and is willing to withdraw this exhibit if that will avoid taking Major Armstrong's testimony.

The Court: Is that consented to?

Mr. Darby: Yes, sir. We withdraw Exhibit 237 in this case and 125 in the Interference record.

The Court: Let it be withdrawn.

IRVING LANGMUIR, resumes the stand.

CROSS-EXAMINATION (Continued).

By MR. RICHMOND:

XQ. 417. After the puncture of the tube of August, 1912, which was mentioned before lunch, and after its repair with balsam as you have stated, or I should say before the repair with balsam, the pressure in the tube came up to atmospheric pressure, I suppose, is that correct?

A. No, it did not. A perceptible increase in pressure had been observed on the McLeod gauge.

XQ. 418. No perceptible increase in pressure had been observed?

A. No, I say a perceptible increase in pressure was observed when measured with the McLeod gauge.

XQ. 419. The notes show that there was such a measurement made, do they?

A. I do not think they do. It is probable that it was first noticed that the bulb had punctured by the localization of the brush discharge over the surface of the glass at a particular point a little bright spot of light would mark the place that had been punctured. The hole through the glass, however, would be so small that the leakage of air through the hole would be extremely slow and a drop of balsam was then probably placed on that spot and then the Toepler pump was operated until the pressure was satisfactorily low.

XQ. 420. Is your answer just preceding given from independent recollection?

A. Not on this particular occasion, but it had happened I suppose in all a good many times in the course of work that extended over a year or two that bulbs had been punctured by the high frequency discharge.

XQ. 421. You did not bake the bulb out when you re-exhausted it after it was punctured?

A. Not in this case, no. I was only interested in working at that time, I think, at fairly high pressures of gas.

XQ. 422. About how far apart are the filament strands in a forty-watt incandescent lamp where they are attached to the lead-in wires?

A. In the lamps that I used on November 19th, they were probably about a half an inch apart, between half an inch and five-eighths of an inch.

XQ. 423. And the spacing is about the same for commercial lamps at that rating, is it not?

A. I think in commercial lamps they are rather closer together than that.

XQ. 424. How was it before the middle of 1912?

A. I do not remember exactly what was the practice in this regard in commercial lamps. The lamps that I speak of were lamps made in the laboratory for me, special lamps that had been made for me about a year before, that is about 1911. I know it was our practice at that time to have the leads rather further apart than they usually are now and I think than they usually were in commercial lamps at that time.

XQ. 425. And although the wires diverge as they leave the lead-in wires, the average separation of the most positive and most negative strands is about five-eighths of an inch or possibly three-quarters of an inch; is that right?

A. Do you mean the filament wires?

XQ. 426. Yes, the filament wires. You understand that I am speaking of the 40-watt incandescent lamp and not of your lamps, 3, 6 and 2, of November?

A. Yes, I understand that. I should say that the average distance would be a little over an inch, about an inch.

XQ. 427. And in those 40-watt incandescent lamps the length of the strands is about three inches, is that right?

A. I do not know exactly what you mean by strand. There were six loops, each consisting of two legs and each leg I should say would have been a little over two inches in length, roughly two inches.

XQ. 428. It is that length that I want to get. So that as to length of filament and as to separation, these two positive and negative legs in an incandescent lamp simulate at least in a rough way the filament length and separation in your August, 1912, tube; is that correct?

A. The average distance between the two sections of a filament used as anode and cathode in these experiments on November 19th was about one inch and there was a glass stem of about one-eighth of an inch in diameter in the axis of the bulb which separated these filaments. In the experiments in August, in the experiment 317, the filaments were single loop filaments about half an inch apart and were without any glass stem in the bulb, showing in some respects the conditions were considerably different. The diameter of the filament was also quite different.

XQ. 429. You remember that I am speaking of the 40-watt incandescent lamp in general?

A. The 40 what?

XQ. 430. The 40-watt incandescent lamp?

A. The 40-watt incandescent lamp?

XQ. 431. Yes.

A. Are you not referring particularly to those lamps I use of November?

XQ. 432. No.

A. Then I misunderstood your meaning.

XQ. 433. For the 40-watt incandescent lamp is not there at least a rough similarity between the spacing of the most positive leg and the most negative leg, as compared with the spacing of the filaments in your August, 1912, tube, and a rough similarity as to their length?

A. Well, that is only true of the portion close to the leads, the difference, of course, is that in the August experiments, the two loop filaments were in parallel planes, so that the distance between the filaments was practically constant; whereas, in the ordinary 40-watt lamp, the six loops were arranged, you might say, on the sides, as though on the sides of a hexagon, so that the two loops that formed the ends of the filaments were not in the same plane or in parallel planes, but in planes that diverged from each other, so that the ends of the filament that were attached to the lead-in wires were perhaps half an inch apart, whereas the other ends of that same loop were probably an inch apart, and that was not true in the August experiment. There the distance was probably a half inch at both ends of the loops.

XQ. 434. Now, if I remember right, you have testified in regard to the appearance of blue haze in these incandescent lamps before the middle of 1912; that is, when they were commonly pumped and operated at 220 volts, have you not?

A. They were not ordinarily operated at 220, 120 volts was the usual voltage, but the voltage was raised somewhat above that during certain tests. They were usually run for a short time at higher voltage than normal, after being sealed off from the pump, perhaps at 140 volts, or something of that order of magnitude.

XQ. 435. And you testified that you often had blue haze with them in your experimental work?

A. Yes. I have frequently seen blue haze in the lamps.

XQ. 436. And this blue haze flickered on and off, did it not?

A. Sometimes, not always. It would usually start in by being intense, and gradually become less intense, and stop abruptly; in some cases it would re-appear though.

XQ. 437. And the space current that existed after the blue haze went off in those lamps was of roughly the same order of magnitude as in your August, 1912, tubes, was it not, after the current had dropped to the lower value that we have been speaking of?

A. Well, of course, I never measured the space current in the way that I did in August, in the middle of August. That is, in all of those lamps, there is a single filament, so that there was no way of measuring the space current. The only cases where space currents have been measured at all, so far as I know, were in those special experiments when a little auxiliary wire was placed in. It was usually made very small, a small piece of platinum wire, perhaps half an inch long, sticking into the bulb through the glass, and the currents to that would be measured.

XQ. 438-439. But even without measuring, the currents must have been of the same order of magnitude because the voltage difference between the ends of the filament was of the same order, you have pointed out that it was somewhat less, and the spacing was of the same order of magnitude, or a little greater, I think you have indicated?

A. You mean from my present knowledge of the conditions of those lamps?

XQ. 440. Yes, Dr. Langmuir.

A. We can now conclude that the currents must have been of the same order of magnitude. I think that is true.

XQ. 441. I hand you a diagram, on which I have plotted all the points recorded in Sweetser's notes for August and September, 1912, in which the current had low values, which I understand you to say were due to the limitation by space charge, and at least some of those points you have said were substantially unaffected by positive ionization. The table in the diagram gives the pages of Sweetser's notes on which the records are found, and gives the corresponding pressures. With that diagram before you, I will ask you to refer again to page 2091 of the Interference record. First, let me ask you, the line on that page of the Interference record that is drawn with the 3/2 slope does not pass accurately through the two points that are plotted, does it?

A. No, it is drawn the way experimental curves usually are, that is, to fit as nearly as possible the two points, the slope being fixed by the 3/2 power law relation.

XQ. 442. If the line were drawn accurately between the two points it would have a slope of 1.83?

A. If I attempted to draw a 3/2 power slope, the slope would be in accordance with the 3/2 power line.

XQ. 443. But if you attempted to draw a line between the two points and see what slope it would have had, you would find a slope of 1.83?

A. I think I said so in the discussion of that curve. On page 2092, I pointed out that the curve drawn through those two points would be 1.83.

XQ. 444. That is right. That is the figure that I name. And that is the middle line on the diagram that I have just now handed you. But there were other current readings indicated by the other circles on the diagram and these would give slopes ranging all the way from .953 to 2.58, and why did you select that one which gave a slope nearest to 3/2?

A. I did not select one that gave a slope nearest to 3/2. I simply picked out the two runs that were made at the same time, as nearly as possible at the same time. On pages 1177 (Plaintiff's Exhibit 99) and then the run that immediately follows that on page 1178 and I took in both cases the lowest currents recorded in those two runs. That was my reason for taking those points.

Mr. Richmond: The diagram just handed to the witness is offered in evidence as diagram for ten points of Sweetser's notes—I will ask to have it marked for identification as diagram of ten points of Sweetser's notes of August, 1912.

(Received and marked "Defendant's Exhibit J for identification.")

XQ. 445. Then, if these other points that appear on the diagram are to be distinguished as representing the readings that were taken at another time it shows that the behavior of this tube was far from reproducible, does it not?

A. It shows the variations as great as those that are indicated there did occur with the range of pressures that were occurring in that tube.

XQ. 446. And these different values were somewhat dependent then, you think, on the difference of pressure at those different occasions; is that correct?

A. I think so. The variations are small compared with the differences between these readings and the sixteen and seventeen milliamperes that was observed just before the pressures went down to that value.

XQ. 447. But large as compared with one another?

A. Large to the extent as shown on the diagram. I do not think that all of these points were independent of the positive ionization to the same extent. I think the ones I picked out for plotting were much more nearly free from the effects of positive ionization than the other ones.

XQ. 448. Why do you think so?

A. Because they gave lower values and I naturally picked out the lowest values in any given series of readings. I had the two series that I was considering and I gave the lowest current values because those were the most free from positive ionization.

XQ. 449. But it seems to me that in view of this great variety among these readings you must have been in considerable doubt as to whether those were indeed the lowest possible values?

A. I picked out, I said, the lowest values in those two series of readings on pages 1177 and 1178 and I was not considering any others.

XQ. 450. And if the vacuum had been further improved there may have been lower values still?

A. Not appreciably. I said before that there might have been some perhaps 10 per cent. lower. Ten per cent. is about the accuracy of the readings. Of course, the two voltages, 200 volts and 250 volts are not very far apart. So that it does not have much significance to try to calculate the exponent from those two values.

The point is that the measurements of current are consistent with the 3/2 power law within the experimental error, and that the data as far as they go constitute evidence that the tube was following the 3/2 power law not with a very high degree of accuracy but with as good a degree of accuracy as the measurements permit, considering the errors that might take place in the readings.

XQ. 451. I want to come back to the matter on which I was questioning you a minute ago. The current between the most positive and most negative legs of the incandescent lamp, after the blue glow cleared up, you considered to be limited by space charge, did you not?

A. Do you refer now to the 40-watt tungsten lamp?

XQ. 452. Yes, and particularly about your experience prior to the middle of 1912.

A. In a well-exhausted lamp after it had been run a long time and the blue glow had disappeared, what current there was, from one end of the filament to the other, was limited by space charge.

XQ. 453. Referring to this diagram for the August, 1912, work, which is Plaintiff's Exhibit 163, you did not make any such diagram as that in 1912, did you?

A. No.

XQ. 454. When did you first have occasion to make such a diagram plotting the pressure against the Edison current?

A. Three or four years ago I made such a diagram from those data.

XQ. 455. After the current got down to the low value in this August, 1912, tube as you have testified and as shown on this Plaintiff's Exhibit 163, what did you do with the tube or what did Sweetser do with it?

A. We continued to study the clean-up of nitrogen with different currents and voltages and filament temperatures.

XQ. 456. That is, at once you admitted more nitrogen?

A. Yes.

XQ. 457. And that completely neutralized the space charge effect for the current immediately thereafter?

A. It brought it back in the condition in which it was in before.

XQ. 458. Do you consider that absence of blue glow is a false earmark of a pure electron discharge substantially unaffected by positive ionization?

A. Not necessarily false. It is not a question of falseness but of the usefulness of the test. It may be sometimes a useful test and at other times it may mean almost nothing. In itself blue glow is of no importance. It only has significance in connection with what it may indicate as to how the characteristics of the tube would be affected by the ionization that is indicated by the blue glow.

XQ. 459. When blue glow is manifest you are tolerably sure that you do not have a pure electron discharge, are you not?

A. Not necessarily. The blue glow indicates something quite different from the things that determine whether or not you have a pure electron discharge. Of course, the word pure is always a relative term which denotes a comparison between one thing and another. When I talk of pure electron discharge I have usually meant a discharge in which the effects of ionization do not materially influence the usefulness or characteristics of the device as it is to be used. That is what I think we always mean by purity.

XQ. 460. I need to get my thought cleared up on that because I had supposed that under some circumstances very gassy tubes were useful so that it does not seem to me that you can say that this whole question is settled by whether the tubes are useful or not, can you?

A. As I understand it, you are referring now to the term pure electron discharge?

XQ. 461. Yes.

A. As I understand the word pure it means free from harmful ingredients or harmful effects and of course that necessarily implies that the very word harmful means harmful for some purpose.

Ionization always occurs in all tubes at voltages materially above the ionizing voltage. So to some extent no electron discharge can be absolutely pure. There will always be some ionization. So that by the word pure we necessarily mean free from ionization to an extent that is such that the ionization bring about no harmful or deleterious action.

XQ. 462. Does the ionization in the General Electric Tungar rectifier lead to a harmful result?

A. No, but there it produces a definitely useful result, so that of course we would not talk about a pure electron discharge because an electron discharge free from ionization could not be used in a Tungar rectifier at all. The discharge in the Tungar rectifier requires absolutely the presence of positive ions.

XQ. 463. It seems to me that if the definition of "purity" is just to be that the ionization is not harmful, then your Tungar rectifier would be regarded as pure?

A. Perhaps I have not made that quite clear. By the term "pure" in general, I think we mean "free from impurities in amounts that are important." That is, it implies the idea that a further removal of impurities would not change the usefulness of the device or the object. We talk about a chemically pure substance, for example. Nobody means for a moment that it has no impurities. They mean that it is at least so pure that it would be immaterial to make it purer, and the same is true, I think, of an electron discharge. An electron discharge can be said to be pure if a further reduction in the amount of ionization would be practically immaterial. Now, of course, that is not true of a Tungar rectifier. It is not at all immaterial; it is absolutely necessary in the device.

XQ. 464. I do not remember, your Honor, whether a Tungar rectifier has been explained. It has been mentioned in this record, and I will ask Dr. Langmuir briefly to explain what it is.

THE COURT: What is the word?

XQ. 465. It is a coined word, a contraction of tungsten and argon, I think; is not that right, Dr. Langmuir?

A. That is right. After we built high vacuum devices and became familiar with the space charge effect, as the space charge of electrons, which limited the current to rather low values, we realized that the usefulness of the rectifier, for alternating currents, utilizing the pure electron discharge, was practically limited to high voltage work because the currents were small, and to get large energy, you would have to use high voltages, and as a result, we developed a high voltage device, which we called a kenotron, which we used up to 100,000 volts. The reason that such devices were not useful on low voltage circuits such as 110 voltage circuits, with large currents, such as 5 or 6 amperes, was that the electron space charge prevented more than a few milliamperes from flowing at those low voltages. To make a practical rectifier that would be suitable for low voltage, it was therefore necessary to eliminate space charge, and we therefore started experiments to see whether we could eliminate space charge, in a rectifier, without sacrificing life and other factors. So we put in different gases, and among the different gases that we studied, we found argon was the most suitable, and we found finally that the best pressure to use was about 5 centimeters pressure, 50 millimeters pressure of argon. This pressure would eliminate space charge practically entirely, and allow us to get a current of about 5 amperes with a voltage of about 8 volts. We thus made a perfectly good rectifier; and these were developed commercially and have been put on the market as rectifiers for charging storage batteries, for example, from alternating currents. Now, these devices absolutely depend on the presence of ionization for the elimination of space charge.

XQ. 466. I understood you to say just a few minutes ago that you can have a pure electron discharge in the presence of visible blue haze; did you say so? Did you mean that?

A. I meant to say that you might have such a discharge. I do not see any reason why you should not have such a discharge.

XQ. 467. Will you please tell us under what circumstances?

A. Well, I have seen such a discharge myself in the case of a hot filament, in the presence of alkali metal vapors in which the blue glow could be distinguished in a very dark room, but where the characteristics were in all other respects characterized by the pure electron discharge. The blue glow, which was very faint, occurred in a device in which the current was certainly limited by space charge independently of ionization, as the ionization had no appreciable effect on the volt ampere characteristics.

XQ. 468. Well, then, you will agree that it is very exceptional to have a blue glow except when it indicates substantial ionization, will you?

A. I think that is true.

XQ. 469. On the other hand, I think I have heard you say that the absence of blue glow does not prove substantial freedom from ionization effects; is that correct?

A. Yes.

XQ. 470. Now, with those two statements in view, do you consider that blue glow is a false or a true earmark of a pure electron discharge substantially unaffected by positive ionization?

A. I do not think you can talk about it being false or true, any more than you can talk of a foot being false or a true measure of length. It is a question of its sensitiveness and its accuracy. It may sometimes be a good test and at other times not be, depending on the conditions. In itself, it is of no importance. It is only what implications you can draw from it, and sometimes you can draw such implications, and sometimes not, depending on the magnitude of the current, for example, particularly the magnitude of the current and the voltage. The higher the current becomes the higher the voltage becomes, the better the blue glow becomes as a test of how much ionization, that is ionization which is sufficient in amount I mean, to partly neutralize space charge.

XQ. 471. When you make a plot of current ordinates against temperature abscissæ for a two-electrode tube showing how the current increases faster and faster with increasing temperature, then if the curve of that plot eventually bends over and becomes approximately horizontal, as on pages 134 and 135 [illegible] your notebook. Exhibit No. 81 on the motions——

A. Is it not 133 and 134?

XQ. 472. May be.

A. The curves are on pages 133 and 134.

XQ. 473. Those are the curves which I mean.

A. Here is the notebook (indicating).

XQ. 474. I say, if those curves eventually bend over and become horizontal, that proves that the current is then limited by space charge substantially unaffected by positive ionization, according to your view, does it?

A. Well, it proves it is limited by electron space charge, but there may be a certain amount of positive ionization, not very great.

XQ. 475. Well, is it great enough to be substantial?

A. I think it might be in some cases. I do not think it was in this case.

XQ. 476. Can you give us any idea of how to distinguish cases? I thought I had heard this referred to as a true earmark of the invention, and I should like to know whether it is that?

A. I think it is. But I do not think it is quite as good an earmark as some others.

XQ. 477. Do you think that sometimes it would break down?

A. Not break down, no. But not be very sensitive. That is, there may be enough ionization to cause a moderate, a small increase in current over what it would be without ionization, and still get a flat top temperature curve.

XQ. 478. How moderate or how small?

A. Oh, I do not know how great it might be made in certain cases, but I think not very many per cent., 20 per cent. possibly in some cases.

XQ. 479. Possibly 20 per cent.?

A. I do not know of any cases where it has been bigger than that.

XQ. 480. Now, if you use different voltages—you see, I have been speaking of one voltage up to this point?

A. Yes.

XQ. 481. But if you use different voltages, then, at each voltage, the flat portion will be at a different level, the level being higher the greater the voltage, is that correct?

A. Yes.

XQ. 482. The only factors determining the constant current value in the tube at each of these levels, are the space charge effect and the applied voltage, are they?

A. Well, in some cases, of course, if there is more than one electrode, the voltage is on all the electrodes and may have to be considered. In some cases the charge is on the walls.

XQ. 483. We will confine ourselves to two electrodes then. Referring to these curves that I pointed out in your notebook on pages 133 and 134, I understand you believe that the current values corresponding to the horizontal parts of the curves, represent pure electron discharges substantially unaffected by positive ionization; that is correct, is it not?

A. Yes.

XQ. 484. Why do you think so?

A. In the first place, because they are flat-topped. In the second place, because they vary with the voltage in the way that I know they would vary if they were pure electron discharges. Third, I know that the method of producing the vacuum that I used was ample. It was good enough to get a pure electron discharge.

XQ. 485-6. Now, please refer to your *Physical Review* paper of December, 1913, on page 453. This shows a series of such flat-topped current temperature curves, does it?

A. Yes.

XQ. 487. And does that prove to your mind that in that connection you had a pure electron discharge substantially unaffected by positive ionization?

A. Yes.

XQ. 488. Now please refer to page 463 of the same paper. There again you see a flat-topped current temperature curve marked IV with the pressure noted as .006 millimeter of hydrogen and a voltage of [illegible] volts. Does that prove you then had a pure electron discharge substantially unaffected by positive ionization?

A. It would take me some time to see just under what conditions these curves were obtained. I do not remember them at the present time. I really cannot tell because I do not know just in what order those experiments were made. I think the curves were obtained in experiment 317 and they were made apparently at different times.

Curve No. 1 and curve 3 are described at the bottom of page 46 and curves 2 and 4 are described at the top of page 464.

Now, I do not know whether the geometry of the tube was the same in both those cases or not. The filaments may have been at different distances apart because in that experiment we used magnetic fields and by using magnetic fields, while the current was passing through the filament, we bent the filaments out of shape and changed the distances apart.

The flatness of the temperature curve is an indication that the current is limited by space charge. There is no doubt about that. To what extent positive ionization may have influenced these results I am not able to say definitely without making an examination of the original records and finding out under what conditions the data was obtained.

XQ. 489. Where does the paper tell about these magnetic fields?

A. I do not think they are mentioned. I do not believe they are mentioned in the *Physical Review* paper; they may be, however. I do not know.

XQ. 490. You do not know that there was any change at that then, do you?

A. There may have been and there may not have been. I can find out by referring to the experiment 317.

XQ. 491. Then please refer to that and find out.

A. It will take quite a while. I mean I will have to identify those curves from the data that were taken there with particular sets of data and I think it should take two or three hours to do it. I may have to look through a great may curves to find out just what things these curves came from. I think I can answer what you probably want to know without going back to that actual experimental curve.

I think I have already stated that the flat-top temperature curve is of course conclusive proof that the current is limited by electron space charge. There may however, have been a certain number of positive ions co-operating with the electrons and modifying the space charge. Just how far that effect may go I do not know.

It is certainly a small effect compared—that is the extent to which positive ionization would modify those currents is I believe small compared to the extent to which ionization affected any prior art devices of the same character.

To that extent the type of discharge described here is new, I believe. This is one of the characteristics of the work that I had done which distinguishes it from all prior work.

It is however not a sensitive test. It is not as sensitive a test for the purity of the electron discharge as for example, the 3/2 power law. It is a test sufficient to distinguish a device of this character from prior art devices such as the audion.

XQ. 492. Would you say that it was a very insensitive test then?

A. Sometimes I think it is quite sensitive and at other times it is not. I have not made a very careful study of that particular point.

XQ. 493. Perhaps this is one of the cases where it is very insensitive; is that correct?

A. I do not know. I think that by referring to the original notes I might be able to form some idea as to whether or not there was enough positive ionization to have any appreciable effect on the current in the curve that you have shown me, but without finding out more about the device or the conditions under which those experiments were made, I do not feel able to tell you just how much effect positive ionization may have had.

XQ. 494. Is that a common practice for you to vary the conditions of an experiment as you suggest in this instance of changing the spacing of the filament by means of a magnetic field and not report on it in the paper that you present?

A. This paper is a short summary of a very large number of experiments that were made and the curves, as far as I know, 1 and 3 and 2 and 4 are simply for convenience placed together in one curve. They are referred to and described in different places in the text. For example, one comes under the heading of the general effect of residual gases on the constants of Richardson's equation and the other one is described under the heading of hydrogen. As far as I know, at present there is no direct connection between those two sets of curves. They may have been taken under very different conditions.

The experimental work I might say that was done in our laboratory was not done for the purpose of writing this paper in the way most papers are written which result from college laboratories where scientific work is usually done for the purpose of writing a paper about it. This work was done in order to get information on the subject and an amount of material had been gathered together which was perhaps ten times as much as would have been accepted for publication by the *Physical Review* and so I simply had to select here and there experiments to illustrate different points that I wished to discuss.

For that reason these different things may appear to be rather disconnected. It is nowhere in the paper stated that they are to be connected as far as I know. The order in which the experiments were made may be very different from the order in which they are described.

XQ. 495. That flat-topped curve on page 463 of your paper to which we have been referring marked IV, was at what pressure in microns?

A. The pressure there is given of six microns of hydrogen.

XQ. 496. Do you doubt that it is given correctly?

A. It probably is correct. The pressure may have varied in the course of the run somewhat, and if so that would have been the average pressure during the run.

XQ. 497. And this was a tube with two hairpin filaments, was it?

A. Yes.

XQ. 498. And have you been accustomed to get pure electron discharges substantially unaffected by positive ionization with pressures as high as six microns in such tubes?

A. Not as a rule, no.

XQ. 499. As an exception, then.

A. Of course six microns of hydrogen is only equivalent to about one micron of other gases because hydrogen has very much less effect on ionization than other gases have. I think it is improbable that the current was substantially pure electron discharge under these conditions.

XQ. 500. Why is it that hydrogen has this reduced effect that you have mentioned?

A. There are two or three reasons. In the first place the hydrogen molecules are relatively small compared to the molecules of other gases, so that the chance that an electron will hit one of them is less than if the molecules were larger. The electrons travel much bigger distances through hydrogen before they collide with them.

Then hydrogen does not ionize quite as readily as some other gases even when the collision does occur. The first factor I think is the most important one. Hydrogen, being the element of lowest atomic weight, has molecules much smaller in size than other molecules.

XQ. 501. Now, on that same figure on page 463, the curve marked III has another nice flat-top, which in your view, I understand, indicates that there was then a pure electron discharge substantially unaffected by positive ionization; is that correct?

A. I think so.

XQ. 502. And in this case the heights of those two curves, their levels go just the opposite way from the rule that you stated a little while ago; that is, the higher the voltage the lower down the curve?

A. Yes.

XQ. 503. This forms a very notable exception then to the rule that you endorsed a few minutes ago?

A. It does unless the electrodes were a different distance apart. The difference of the magnitude of those curves may be due perhaps to the fact that the electrodes were different distances apart.

XQ. 504. Can you think of any other reason?

A. The only other reason I think of is that there may have been ionization enough at the higher pressure one to cause a decrease of current.

XQ. 505. That is, since there was more pressure on the higher one even though the voltage was less, you think that may account for its being higher?

A. I think it may perhaps be possible.

XQ. 506. Then it is not a very dependable earmark for the presence of a pure electron discharge substantially unaffected by positive ionization if a change of pressure can work oppositely to a change of voltage like that, is it?

A. It is not as good as some other tests. That is what I said in the beginning. I rather doubt if that whole effect is due to ionization. I also doubt if that effect would occur to anything like the same extent in devices in which there are plate-shaped anodes.

XQ. 507. What effect?

A. I refer to the fact that a certain amount of ionization may occur in the presence of gas which may increase the current on the flat-top saturation part of the curve by a certain amount.

XQ. 508. Your November, 1912, tubes did not have plate anodes, did they?

A. No.

XQ. 509. They had hairpin anodes just like this one in the *Physical Review* paper, didn't they?

A. Yes.

XQ. 510. Now, please turn to page 470 of the same paper of December, 1913. I direct attention to the curve marked III. In this case the currents are plotted not against temperature as in the cases we have just been considering but against volts. And here I read from the paragraph just below the diagram:

> "The lower part of curve III, if obtained in a perfect vacuum, should therefore follow equation 11" (which is your space charge law equation). "In other words, the current should increase with $V^{3/2}$. By plotting the first six points of this curve on logarithmic paper, a straight line was obtained, but the slope, instead of giving 3/2 as the exponent of V, gave 1.71. This difference is certainly due to residual gas."

If that is the case, how is it you can point to an exponent of 1.83 for your August, 1912, work with just the same kind of a tube and say that that is a satisfactory indication that you had a pure electron discharge substantially unaffected by positive ionization?

Mr. Davis: I dislike to interrupt the cross-examination, but I think my brother should show the witness where he made the statement before he challenges it.

(Discussion)

Mr. Davis: It seems to me it is quite different from what Mr. Richmond suggested he said, that is all.

Mr. Richmond: All right. I will drop that question.

XQ. 511. What does that page that I have just referred to in the Interference record mean, or what does it prove, Dr. Langmuir?

A. What page?

XQ. 512. Page 2091?

A. Page 2091 is a plot on logarithmic paper of the two points that were obtained at two different voltages, 200 and 250 volts.

XQ. 513. Does it mean anything or prove anything in this case?

A. It proves that the points agreed with the 3/2 power law, within the experimental error.

XQ. 514. Then which are you testing there, the tube or the 3/2 power law when you made that plot?

A. We were testing the tube.

XQ. 515. Testing the tube?

A. Yes.

XQ. 516. And you say it is a high vacuum tube, because it conforms to the 3/2 power law; is that right?

A. The accuracy with which those points agree with the 3/2 power law is such that no sharp distinction can be drawn between 1.5 or 1.8. Both are within the experimental error of the measurements.

XQ. 517. But the experimental error might be the other way, might it not, and it might be as far off as 2.0?

A. Possibly, yes.

XQ. 518. Are you not taking advantage of the experimental errors to prove your case instead of to disprove it?

Mr. Davis: If your Honor please, I object to that question.

(Discussion)

The Court: Assuming that he had stopped there, I am not ready to say that was the whole substance of it, and I think the cross-examination then is material.

Mr. Davis: If your Honor so decides it.

The Court: Read the question, Mr. Smart.

(Question repeated as recorded.)

A. No.

XQ. 519. If the experimental error necessary to get from 1.83 back to 1.5 is 0.33, that same experimental error the other way would get you to 2.16, would it not?

A. Very likely, but either one lies within the experimental error in this particular case.

XQ. 510a. Do you think it proves such of anything in regard to the character of the tube in August, 1912?

A. Yes, I think it proves quite a good deal. Not as much as though I had taken ten points over a curve, as for example, it certainly would not prove as much as though I had taken a whole set of points running from less than 10 volts up to 100 volts as I did in the curve of the *Physical Review* paper on 470. Of course, the more points you have, the more definite conclusions you can draw and the more accurate the results agree with the theory the more definite conclusions you can draw.

XQ. 511a. Then is this the situation: That when you get 1.71 pretty definitely, it means that the difference is certainly due to residual gas, but when you get 1.83 indefinitely, it means that there was no effect due to residual gas?

A. It means with a certain probability, as in all experimental results. No experiment, or set of experiments, indicates anything with absolute certainty. It is a question of probability, and here there is a very considerable probability, that we did have the 3/2 power law followed just because those readings came out the way they did. It is not absolute proof, a mere strong probability.

XQ. 512a. I wish you could show it to us.

A. Well, I think the testimony I have given is ample too. I think I have stated very frankly just what the results should be taken to mean. They do not mean anywhere near as much as though I had taken complete data, complete curves; but to my own mind, there is not the slightest doubt but what I did have, and the results taken together, prove that I had a practically pure electron discharge in that device at 250 volts.

XQ. 513a. But I want to know what this particular result proved?

A. It is part of the proof. It does not prove it by itself; it is just one of the factors that go together to help make that conclusion. If I had nothing but just those two points, I would not consider the evidence to be very strong. It is that evidence, backed up with all the rest of the things that we knew about that tube—it is cumulative evidence. That is true of nearly all scientific work. It takes several different lines of research to prove a definite point. No one single thing is likely to make you certain of a conclusion. The real trouble with these measurements was, that they happened to come too close together in voltage, 200 volts and 250 volts are really not far enough apart to determine the slope of that line, with anything more than a rough degree of accuracy.

XQ. 514a. Then, why did you put that in your testimony?

A. Because it is significant, very significant.

XQ. 515a. In the Interference record, at the lower part of page 1589, you said that, certain work progressed rapidly, so that, long prior to October, 1913, we had built a large number of pliotrons, in 4- to 7-inch bulbs, which operated with anode voltages of 10,000 to 20,000 volts without showing the slightest signs of blue glow or other effects of positive ionization; are any of those in evidence?

A. I do not know just what you mean by "in evidence"?

XQ. 516a. Have any of those been produced in this case?

A. No. I have testified in regard to the first one of them, the tubes themselves are not in existence, I think.

XQ. 517a. And at the bottom of page 1590 of the Interference record, you said:

> "Long prior to October, 1913, we also built two electrode devices or kenotrons having plate-shaped anodes for the purpose of rectifying high-voltage currents with considerable power."

Are any of those in existence?

A. I do not believe so.

XQs. 518a-519a. And at top of page 1591, you said:

> "Long prior to October, 1913, in our work with high-voltage pliotrons, we found that we were able to use these devices for the production of high-frequency oscillations."

Those were the same ones referred to at the bottom of the preceding page, were they?

A. Why, no. At the bottom of the preceding page, it referred to kenotrons, which are two-electrode tubes.

XQ. 520. These are something different from those that I have mentioned just now. Then, are these the high voltage pliotrons, or were they the same as these——

A. They were the ones referred to at the bottom of page 1589.

XQ. 521. Very wall, and the earliest operative tube that you have produced as an exhibit in this case, is the one that was made in April, 1914, is it not?

A. Will you please read that question? (XQ. 521 repeated as recorded.) You mean by "operative one," that can now be operated?

XQ. 522. Yes. You may refer to page 1591 of the Interference record.

A. Yes. I think that is true. I think it is the only tube that we have produced that is operative.

XQ. 523. Are pages 1592 and 1492 of the Interference record——

A. Might I add in regard to that other question, of course I mean other than the commercial tubes that were discussed in the record for the purpose of getting the characteristics.

XQ. 524. And came considerably later?

A. Among the historical tubes of early date that was the only one which was produced as an exhibit.

XQ. 525. And this one that was made in April, 1914, was tested, the test running up as high as fifty volts, and that test is shown on pages 1592 and 1593 of the Interference record, is it?

A. Yes. The current was twenty milliamperes at fifty volts.

XQ. 526. And the grid was connected to the anode, was it not?

A. Yes, so as to be able to use it as a two-electrode tube.

XQ. 527. Which of those three lamps, distinguished as 3, 6 and 2, is shown in the photograph on page 1982 of the Interference record——

A. I have no way of telling.

XQ. 528. Do you recall the photograph? I have given the wrong page, your Honor. I can turn to it very rapidly.

A. This is it (indicating).

The Court: Page 2096.

XQ. 529. Thank you. On page 2096.

Mr. Davis: Now, let the question be read. I have not followed it.

(XQ. 527 repeated as changed as follows: "XQ. 527. Which of those three lamps, distinguished 3, 6 and 2, is shown in the photograph on page 2096 of the Interference record——

"A. I have no way of telling.")

XQ. 530. In those experiments with lamp No. 2 in November, 1912, I understand that sometimes you used one of your two anodes and sometimes the other anode, and sometimes both of them connected together as one anode. When you used only one, how was the remaining one disposed of? Was it connected in any way?

A. No, I think it was allowed to float.

XQ. 531. And did it charge up negatively?

A. It would charge up to about approximately the negative end of the cathode.

XQ. 532. And did it then exert a grid action on the current that was flowing?

A. To some extent, yes.

XQ. 533. I understood you to say that your work of November 19th, recorded shortly thereafter in the year 1912, was so important that you wrote twenty pages of notes about it; was it important enough to disclose it to any one?

A. Yes. I discussed it with a great many people in the laboratory.

XQ. 534. To whom did you disclose it?

A. Probably to pretty nearly every one around that I was working with.

XQ. 535. Give us half a dozen names?

A. Mr. Sweetser, Mr. Mackay, and then at later times, I think it was the next day, we had a lamp committee meeting at which I discussed the results that I had obtained. There were several men present at that time. Later on, after I had obtained more complete data in this experiment 317, I talked it over with Coolidge and I certainly must have talked it over with Dr. Whitney, although I do not have any distinct recollection of the time. I know Dr. Whitney was thoroughly familiar with the work that I was doing.

XQ. 536. Mr. Sweetser is the only one of those who has testified as a witness in this case, is he not?

A. No, I think Mr. Mackay testified in addition to Mr. Sweetser and possibly Mr. Robinson testified.

XQ. 537. It was the practice in your laboratory for Mr. Gartner to witness your notebook whenever you recorded an invention in it?

A. From time to time Mr. Gartner might if he happened to come around the laboratory, he might witness some pages in my notebook. It would not have to be Mr. Gartner. Anybody might do so. I had no very definite system in regard to that.

XQ. 538. On page 2128 of the Interference record Mr. Gartner entered a table of places where he had signed as a witness in your notebook, did he not?

A. I do not remember.

XQ. 539. Here it is.

A. Yes.

XQ. 540. Did any one sign as a witness for these twenty pages of such importance in November, 1912?

A. I do not think so.

XQ. 541. On your direct deposition I understood you to refer to a book by Wilson as a source of information. I hand you Defendant's Exhibit I for identification and ask you if that is the book.

A. Yes, that is the book. And the equation given at the top of page 7 of that book is the equation which I copied into my notebook in the middle of page 123.

XQ. 542. And on the opposite page of that notebook which was published in that same year it says:

> "The variation of the thermionic current from hot platinum in a vacuum with the temperature of the platinum was first investigated by O. W. Richardson, who at the same time put forward an elegant theory to account for it which is now firmly established."

Is that correct?

A. Yes, you have read correctly from page 6 of this book.

MR. RICHMOND: For my information, Mr. Davis, have you introduced the paper by Wilson on which you rely for your statement that Wilson doubted Richardson's law or something of that sort?

MR. DAVIS: I am not relying on this paper but on Arnold's own statement to the Commissioner of Patents in one of the early papers in his application file.

MR. RICHMOND: And you do not pretend to produce the paper by Wilson?

MR. DAVIS: I do not know. Mr. Lunt may know, but I have not been looking after these things. I will try to find out for you.

MR. RICHMOND: At your convenience, Mr. Davis.

XQ. 543. When you had your notebook before you, you referred to a part of it where the mathematical work was done by you for calculating the 3/2 power law for parallel plate electrodes and I understood you to remark that that part of the work had previously been done by Child. Then I understood you to refer to some more computation for the case of the cylindrical anode and the axial cathode. Will you please point that out again for me?

A. The place in the notebook where those calculations occur?

XQ. 544. Yes, Dr. Langmuir.

Mr. Davis: In accordance with Mr. Richmond's request, I do not find in the list of exhibits this Wilson paper in question, and I do not know whether it will be introduced or not.

Mr. Richmond: Thank you, Mr. Davis.

The Court: Suppose we take our afternoon recess now.

(After a short recess.)

(XQ. 543 was repeated by the stenographer.)

A. The equations applying to this case are worked out on pages 313 to 323 of my notebook 413 under date of February 28, 1913.

XQ. 545. And does the final equation, that is, the conclusion of this line of inquiry appear on those pages and if so point it out particularly.

A. Well, at about three-quarters of the way down, page 320, is given the equation in terms of a quantity which is designated by β, the Greek letter Beta, and then about 6/10 of the way down the page 321 the full equation is written out in which for β is substituted its value in terms of the radius of the cylinder of the filament.

This form of the equation is not very convenient for use when the wire is a very small wire or when you are dealing with a small wire in the axis of the cylinder because it is difficult to calculate an accurate value of β for use in the equation in that case without adding together a great many terms of the mathematical series.

Therefore I set Mr. E. Q. Adams, who was working for me at that time, to work, shortly after that, to devise a better way of calculating the value of β for the case where you are dealing with a very small wire in the axis of a cylinder, and he did that, and the results of the calculations he made were published in the form of a table in my *Physical Review* article on page 458.

The lower values of β^2 squared that are given in that table can be calculated directly from the mathematical expression that I gave in my notebook. But the higher values given in that table, although they theoretically could be obtained from that expression, it would be rather difficult to do so. Mr. Adams found an improved method of calculating them.

XQ. 546. Then the matter was not worked out to an equation in your notebook as it appears in your *Physical Review* paper of December, 1913?

A. The correct equation was given. But Mr. Adams worked out a much more convenient method of obtaining the numerical values.

XQ. 547. I understood you to say that this work on the case of the cylindrical anode and axial cathode was "new, that is, so far as I know, nobody had worked it out." Do you mean that you did not know that Arnold worked it out at an earlier date?

A. No, I did not know that, or at least, if I have ever known it I had forgotten it. I do not remember at all when Arnold worked it out. In fact, I do not believe that Arnold did work it out. It seems to me that it was Kendall as I remember the record. I do not remember the date at which he did that.

Mr. Richmond: Your Honor, I would rather not enter on that discussion.

The Court: Do you make a motion?

Mr. Richmond: I move to strike out the last part of the answer.

The Court: Will you begin the reading of the answer? (Answer to the last question was repeated by the stenographer down to "or at least if I have ever known it, I have forgotten it.")

THE COURT: The remainder of the answer is stricken out.

XQ. 548. I would like to call your attention back to that figure on page 470 of your *Physical Review* paper of December, 1913, for a point that I should have called your attention to in order, but I lost sight of it for the moment. Please notice this curve III, for which you say in the paragraph right below the figure:

> "The slope, instead of giving 3/2 as the exponent of V, gave 1.71. This difference is certainly due to residual gas."

Is it correct that the gas pressure for this curve was sixteen-hundredths of a micron of nitrogen?

A. That is the pressure that is given on the figure, yes.

XQ. 549. And it was nitrogen gas that you used in August, 1912, was it?

A. Yes.

XQ. 550. And this pressure compares how with the pressure that you had in August, 1912?

A. The pressures in August, after the sudden decrease in the current curve varied from about half a micron down to about one-third of a micron, I think, so that the pressure was from two to three times greater than the pressure designated on curve III.

XQ. 551. When you tried to make the vacuum worse for certain of those so-called lamps of November, 1912, was that with all three of them that were numbered 3, 6 and 2?

A. With lamp No. 3 I do not believe that I made any effort to make the vacuum worse in order to study the changes in the conditions. At least, there is no record of it in the notes. With lamp No. 6, as described on page 128, I did do so, by heating the bulb with an alcohol flame, and the same is true of lamp No. 2, which is the third lamp tested. That was both heated and sparked.

XQ. 552. Now, in your testimony you said that you burned out the intermediate section of the filament for two purposes, namely, to get separate electrodes and to affect a clean-up; is that correct?

A. Yes.

XQ. 553. And you recorded in your notebook only the first purpose; is that correct?

A. Yes.

XQ. 554. But you did make an entry in your notebook about "clean up" in connection with blue glow, did you not?

A. I think so.

XQ. 555. And at what stage did this clean-up that you mention occur, and with which lamps?

A. I think it may possibly have happened during certain stages of the early exhaust in each of the lamps, as for example, during the aging of the lamps, when they were first run up to—I may say, for example, when they ran up "to double voltage for one or two minutes to age."

XQ. 556. What page, Dr. Langmuir?

A. On page 124, the bottom of page 124 I say:

> "Running up slowly to avoid arcing."

That is the voltage across the lamp was run the double normal voltage which was probably 240 volts, and that is an extremely high temperature of the filament, four or five hundred degrees above normal operating temperature, so that tungsten vaporizes very quickly at that temperature, and when a gas is contained there, there may be some glow discharge or some positive ion bombardment, which would greatly increase under those conditions the rapidity of the clean-up gas, and then after that, the middle section of each lamp was burned out, one of the sections of lamp No. 2 was burned out during that aging process. Now, after that, in No. 6, blue glow occurred again in flashes as described on page 128.

XQ. 557. Did that improve the vacuum?

A. Yes, the vacuum ended up by being quite high, especially after the tip of the bulb was immersed in liquid air.

XQ. 558. Does your notebook say anything about blue glow, or about improving the vacuum in connection with the aging?

A. No, it does not mention that. It merely says "running up slowly to avoid arcing." It may be that no blue glow occurred if the current is run up slowly, it sometimes does not occur, it probably did occur, however. It was usual to observe blue glow under these conditions with lamps exhausted in the regular way that these were exhausted.

XQ. 559. Now, after you had done this experimental work, and after you had written up the experimental part of it, you carefully summarized the work in a series of ten facts, numbered paragraphs on pages 139 and 140 of your notebook, is that correct?

A. Yes.

XQ. 560. And the first of these facts was——

> "At first Edison current follows Richardson's formula well up to a certain temperature. Then suddenly blue glow appears and Edison current decreases greatly. Call this first and second stages."

Is that right?

A. Yes, that is in the notebook.

XQ. 561. Well, your answer suggests that I am wrong about it?

A. I do not know what question you asked in connection with it—is it right—I do not know just what you mean—is what right?

XQ. 562. I will make that clear. It did not occur to me that there was any question about your endorsing the statement, but I will now ask whether you now endorse that statement appearing in your notebook?

A. I think that summarizes pretty well what I observed.

XQ. 563. For the three lamps?

A. I do not know whether all three lamps had that effect or not. I rather think that the first lamp did not show it.

XQ. 564. And in the second paragraph of the facts you said, "In first stage Edison current decreases by raising bulb temperature and vice versa." That is written down so and is a correct statement, is it?

A. I believe so although again I do not know whether I had in mind the first lamp or possibly the last two lamps.

XQ. 565. And the fourth paragraph of facts says: "In first stage the blue glow seems to set in usually when maximum is reached." I have read that correctly and that is a correct statement in your notebook, is it?

A. Yes, that is a correct statement in the notebook.

XQ. 566. And the fifth paragraph of facts——

A. Again I do not know that the first stage really always occurred in all the lamps. There is no evidence that the first stage occurred in the first lamp. I am rather doubtful that it did occur. If it did occur it got over it very quickly.

XQ. 567. And the fifth paragraph of facts reads: "No blue glow during second stage." I have read that correctly and that is a correct statement, is it?

A. Yes.

XQ. 568. It was blue glow that cleaned up those lamps, was it not, Dr. Langmuir?

A. No. The blue glow accompanied the process that caused the lamps to clean up. The cleaning up of the lamp was due to tungsten that had evaporated from the filament as a result of the positive ion bombardment.

XQ. 569. I accept your statement as better and more accurate than the one in my question. And this clean-up that you have last mentioned is referred to in the notes as a clean-up. I refer you to the upper part of page 138 of your notebook. "Blue glow was prominent during this clean up of gas."

A. Yes.

XQ. 570. And any supposed clean-up in connection with the burning out of the intermediate filament is not mentioned in the notebook, is it?

A. I do not think it is mentioned specifically, no. Although that is largely one of the objects. It was the object in choosing those lamps in the beginning for that purpose. If the lamps were once chosen for that purpose the rest had to continue automatically, that is, the filament had to be burned out.

XQ. 571. I have understood you that there were two objects, isn't that correct?

A. There were two objects I had in mind when I chose those particular lamps for this particular experiment, but once having decided that the lamps would be used in that way then of course I could not do anything with the lamps until I burned out the filament in order to get two electrodes and that is the thing that was uppermost in my mind at that time.

XQ. 572. And that is the object that is recorded in your notebook?

A. Yes.

XQ. 573. Just what was it that you showed to Richardson when he visited your laboratory. Was it these three lamps, 3, 6 and 2?

A. I remember telling him about those lamps and showing the curves that I plotted. I do not recall whether I showed him the lamps themselves or not.

XQ. 574. And you do not remember whether you operated those lamps for him or not?

A. No, I do not think I can say that definitely although I do seem to have a recollection of having immersed some bulbs in liquid air when Professor Richardson was there and if so I suppose it must have been those lamps, but my recollection is not very clear on that point.

XQ. 575. If the lamps were spoiled it probably was not one of those lamps, was it?

A. I do not think they were spoiled. Of course, if the lamps were burned out I would not have made any further experiments with those lamps, but I do not recall that the lamps were spoiled.

XQ. 576. I had the impression that something had been said about deliberately overloading them so as to spoil them, is that correct?

A. Not for the purpose of destroying the remaining filament. The central filament was deliberately overloaded so that it was burned out, but there was no object in burning out the filament that was used as a cathode. I see no reference in this notebook to other filaments being burned out and I do not think they were burned out.

XQ. 577. Then it is your impression now that when you got through with those lamps on November 19th as recorded in your notebook within a very few days following, they were left in good condition ready for the kind of work you had been doing?

A. I think that is probable. I do not remember definitely what was done with the lamps after that date. I do not think they would have been destroyed. As I said before, I have a vague recollection of having dipped some bulbs in liquid air to show Professor Richardson some effects resulting from that. It may well have been that they were those lamps or some other lamps somewhat like them, but I am not sure.

I know that the experiment that Sweetser was carrying out at that time as experiment 317 was in progress and I showed Professor Richardson that apparatus and I think at that time we took some measurements on the lamp that was being studied in that way in experiment 317. I know distinctly that I showed him the flat top temperature curve and showed him a lot of measurements that we had taken, probably records of experiment 317.

XQ. 578. Then all the work that you did with those lamps as recorded in your notebook in the days immediately following November 19, 1912, left them in the condition of high vacuum tubes, did it?

A. I think so as far as I remember.

XQ. 579. I understood you to say that the DeForest audion that you worked with in the early part of 1913, had all its leads brought out at one press in one end. Are you sure you are right on that?

A. No. It may be that the filament leads are brought out at the other end. In fact, I think it was probable that the filament lead was brought out at one end and the grid and plate leads from the other, but I am not at all sure.

XQ. 580. I think that yesterday you testified about some General Electric UV-200 tubes containing argon. Have I got the designation right and am I right in my recollection?

A. I think so.

XQ. 581. Were those UV-200 tubes always made by introducing argon?

A. I think so.

XQ. 582. Is it not a fact that at an earlier stage you pumped tubes, I say you, but I mean the General Electric Company, pumped tubes that were structurally just alike and then sorted them and called them UV-200 if they had a poor vacuum and called them UV-201 if they had a good vacuum?

A. I never heard of any such thing being done.

XQ. 583. So that is not to your knowledge?

A. I think that is extremely improbable and I never heard of any such thing being done.

XQ. 584. You testified about a conversation with Alexanderson. Did you testify about that in the testimony taken on the Interference?

A. No.

XQ. 585. In regard to seeing blue glow in a lamp, your work has always been with a brilliant incandescent tungsten filament, had it not, and would not that make it quite difficult to see a blue glow unless it were quite pronounced?

A. It is undoubtedly harder to see blue glow with a tungsten filament than it is with a Wehnelt cathode.

XQ. 586. You have discussed the correction to the 3/2 power law which you sometimes find desirable to make to correct for the drop in the potential along the filament. As I understand it the commutator used in a few instances and which is now an exhibit in this case was used by you as a sort of automatic corrector for this filament drop in the cathode; is that correct?

A. When?

XQ. 587. In connection with exhibits produced in the Interference record?

A. Yes. We wanted to get information as to how the tubes are operating to separate the various disturbing factors that might occur and particularly where the voltage drop in the filament was larger than usual, we frequently used the rotating commutator.

XQ. 588. In the simple case of a two-element tube or in a three-element tube, when the grid is attached to the plate and where the connection to the anode is made at the negative end of the filament, this particular correction can be made by subtracting from the applied plate volts one-half of the filament drop; is that correct?

A. It can, if the voltage on the plate (as measured from the negative end of the filament) is say 30 per cent. higher than the potential on the positive end of the filament. It is not satisfactory if the plate potential lies below the positive end of the filament or very close to it.

For example, if there is a filament having a ten-volt drop and you measure the potential from the negative end of the filament, if you have fifteen volts or more on the plate then it is quite satisfactory to measure the potential from the mid-point of the filament, but if you have seven or eight volts on the plate we should not measure from the mid-point of the filament because there is a certain part of the filament which is not affected at all.

XQ. 589. Your exception represents rather an unlikely case in practice, does it not?

A. But not in the tubes that have been produced in this record. In some cases there were thirty or forty volts drop in the filament.

XQ. 590. Please look at page 1168 and page 1170 of the Interference record. Page 1168 shows the departure from the 3/2 power law when this correction is not made with the rotating commutator and page 1170 shows how much better the points fit the 3/2 power law after you have used the rotating commutator to make the correction. Is this correct?

A. The two points are obtained in the way that you suggest, one with the rotating commutator and the other without the rotating commutator and the curve with the rotating commutator does agree with the 3/2 power law better than the curve taken without the rotating commutator.

XQ. 591. Now, please, turn to page 1176, which follows shortly after in your deposition on the motion. In this case you did not use the rotating commutator, did you?

A. In the preceding one the voltage drop on the filament I think was 21.4 volts. In this case it is 10.8 volts. The rotating commutator was not used.

XQ. 592. Now, I show you a copy of that page 1176, with black ink crosses to show the changes by correcting for half the filament drop, as we mentioned a few minutes ago. Can you readily verify one or two representative points to see if the correction has been properly made in that instance?

Mr. Richmond: Your Honor, Mr. Davis suggests letting this witness go now, and that is agreeable to me.

Mr. Davis: Dr. Alexanderson would like to get home.

The Court: You may call another witness, now.

Mr. Davis: I will ask Dr. Alexanderson to take the stand.

U. S. District Court, Wilmington, Del.,
Thursday, November 4, 1926,
10 o'clock A. M.

SIXTEENTH DAY.

Before:

Hon. Hugh M. Morris,
U. S. District Judge.

Appearances: As before.

The Court: Are you ready, gentlemen? Will you renew the cross-examination of Dr. Langmuir?

Irving Langmuir, resumes the stand.

Cross-Examination (Continued).

By Mr. Richmond:

Mr. Richmond: My impression is there is a question outstanding. It is XQ. 592.

"XQ. 592. Now, I show you a copy of that page 1176, with black ink crosses to show the changes by correcting for half the filament drop, as we mentioned a few minutes ago. Can you readily verify one or two representative points to see if the correction has been properly made in that instance?"

A. I notice that half the drop in the potential along the filament, that is, 5.4 volts, has been subtracted from the observed voltages, and the original points as plotted on the curve have been displaced 5.4 volts to the left, that is, the lower voltages, in order to express the voltages with reference to the mid-point of the filament, instead of the negative end of the filament. As I pointed out in my answer yesterday, this, I think, is a justifiable procedure in this case down to about fourteen volts; that is, down to currents of about fifteen milliamperes; but below that, the potential of the plate is too nearly the same as the potential of the filament to make it justifiable to correct in that way. You will notice that these points go down to observed potentials of six volts, and when the anode was at a potential of six volts it was 4.4 volts *negative* with respect to the positive end of the filament. In other words, it was intermediate in value between the negative and positive end of the filament, and in that case it is not a proper way to correct the results to make the subtraction of 5.4 volts. So that I believe that if a rotating commutator had been used, the curve that would have been obtained by the actual elimination of the voltage on the filament, would have agreed very well with the points that you have marked by crosses at currents above about fifteen milliamperes, but below that I do not think that they would have agreed with the points that you have shown by crosses. At these higher voltages, or with currents above fifteen milliamperes, the displaced curve which you have drawn, would have a slope a little less than that corresponding to the 3/2 power law, and as the voltage is raised, it approaches more and more closely to the 3/2 power law, and there is no indication whatever of a rise above the 3/2 power law at voltages above ionization, such as would have been characteristic of the effect of gas in the tube.

In this case there evidently are two factors that tend to compensate which have made the lower part on the curve come closer to the theoretical 3/2 power law than they would if either one of these factors alone were neglected or eliminated.

XQ. 593. You are referring now to the curve as it appeared originally?

A. Yes. In that case the good agreement with the

3/2 power law at the very low voltages, far below the positive end of the filament, was due to a more or less fortuitous balancing of the two factors.

MR. RICHMOND: I will ask to have the sheet which has just been shown to the witness and on which he based his reply marked for identification.

(Marked "Defendant's Exhibit L for Identification.")

XQ. 594. If I understand you in this case there were some factors tending to cause departures from the 3/2 power law but you consider that somewhat fortuitously they counteracted one another so that you get a tolerable agreement with the 3/2 power law?

A. At the low voltages below ten volts I think that was largely true.

XQ. 595. But how were these factors working at page 1168 to which I referred you yesterday?

A. This curve was obtained with a pliotron or three-electrode tube in which there was an unusually high voltage drop along the filament, the filament voltage being 21.4 volts. This fact caused the lower part of the curve to become unusually steep. According to the theory of the effect of the voltage drop along the filament when the voltages of the plate become below the voltage of the positive end of the filament, the theoretical slope of the line should be 5/2 instead of 3/2 and I think it is for that reason that this slope below about thirty volts, particularly below twenty volts, does become steeper than the 3/2 power law.

That is borne out of course by the comparison of the curve on 1168 with the curve on 1170 where the rotating commutator was used and therefore the effect of the voltage drop along the filament has been eliminated.

XQ. 596. Then, when these factors that tend to modify the expression of the 3/2 power law one way or the other, when they fortuitously neutralize one another so to speak or nearly cancel out, you do not use the rotating commutator, but when they do not fortuitously cancel one another out, you do use the rotating commutator, isn't that right?

A. That is not right. That is not what I do.

XQ. 597. Will you please tell us, then, in general, when you use the rotating commutator in these demonstrations and when you do not use it?

A. As I recall what we did at that time, we first took all the curves of those tubes without the rotating commutator and in certain cases, particularly those tubes that had a large voltage drop along the filament, it was obvious that that voltage drop along the filament was causing marked increase in the slope at the lower part of the curve and in a few of those cases additional readings were taken with the rotating commutator in order to find to what extent the voltage drop along the filament did modify these results.

In the illustration which you have given of type P pliotron which had the highest voltage drop along the filament that any of them have, both curves were given in order to show the magnitude of the effect that resulted from that. I think in some of the other cases we gave curves obtained with the rotating commutator only. To the best of my recollection in all cases where we did use the rotating commutator the curve obtained with the rotating commutator was the one that was given.

I would like to point out furthermore that the significant part of the 3/2 power law plot is in the neighborhood of the ionizing voltage and higher, and in all of these cases, that is, at the voltages above ionizing voltage, that is from fifteen to twenty volts upwards, the effect of using the rotating commutator is relatively small, except possibly in the one case of the type P pliotron, where there is a voltage drop of twenty volts along the filament.

XQ. 598. When did you first become aware, as you have testified, that the particular entries in Sweetser's notebook for August, 1912, relating to the current of reduced value, as is shown in Exhibit 163—when did you first become aware that those entries represented as you have said, "a condition of current flow largely governed by the space charge effect"?

A. Why, of course, by that time I had no idea of the theory underlying these effects. I think I have already testified that it was about the twentieth of November or the twenty-second of November, I believe, when I first had the idea of the cause of the low currents that were obtained as the vacuum was improved. In regard to these particular measurements that you refer to, I do not believe that I thought of those particular measurements as proving that the current is limited by space charge, that is, I had that interpretation of these results until, oh, several years after 1912. I do not know just when. I do not remember exactly.

XQ. 599. Is your memory refreshed as to that date by reference to Mr. Davis's telegram which was filed in the Patent Office, which asked for additional time for an extensive investigation? I think you will notice that the date of that is September 15, 1916, and it bears the Patent Office stamp September 16, 1916 (handing book)?

A. No. I do not remember this telegram. That does not suggest anything.

XQ. 600. That does not help you to fix the date any more definitely?

A. It may be that date, but I do not remember the telegram. That particular telegram does not help me to fix the date, but as far as I know, it may have been that date or thereabouts.

XQ. 601. Referring to your notebook record for lamps 3, 6 and 2, with which you worked on or about

November 19, 1912, does the notebook record show the duration of the clean-up process that you mentioned in your testimony?

A. Will you read that? (XQ. 601 repeated as recorded.) Why, only in one case, I think, and at the beginning of the—may I see the notebooks (inspecting books)? On page 124, there is the description of the aging process, in which the filaments were "run at double voltage," that is 240 volts, "for one or two minutes running the voltage up slowly to avoid arcing." That is the only reference I find to a definite time during which any clean-up process took place. Of course, in a few other cases—I think that is the only definite statement.

XQ. 602. And was it that aging for one or two minutes that affected the clean-up as recorded on page 124, rather than when you "burned out Section B so as to have two separate sections," as recorded on the next page following?

A. No, we cleaned up in both cases. Probably more clean-up during the burning out of the filament. That was probably more effective than the first one.

XQ. 603. Is there any record of filament temperature during this clean-up?

A. No, I think not. Except the fact that it is under double voltage and calculate the temperature from that during the first case. That fixes the temperature definitely. I can calculate what it would be but I cannot give it from memory. The temperature would have been extremely high, probably over 2800 degrees, very likely 2900 degrees.

XQ. 604. Is there anything in those notes for the lamps of November, 1912, that have been referred to as lamps 3, 6 and 2 to indicate that they had any better vacuum than the tube of August, 1912?

A. I know from the method of preparation of this lamp that it had a much better vacuum but the pressures are not given in the notes. There was no way of measuring the pressure so that there is no single definite statement in the notes which tells exactly what the pressure was.

The method of exhaust, for example, cooling the bulb in liquid air and vaporizing large amounts of tungsten, I know is a method of exhaust which would give an extremely good vacuum. I believe that the pressure in the lamp during most of these runs particularly those which are recorded in the curves on pages 133 and 134, I believe that the pressure was considerably below 0.01 micron.

XQ. 605. But so far as the records go, your answer is that there is no indication of a better vacuum than in August, 1912?

A. The agreement with the 3/2 power law is sufficiently good to make me believe that the pressure from that fact alone was lower than 0.3 of a micron, somewhat lower than that.

XQ. 606. Then you mean in November, 1912, you think there was much better agreement with the 3/2 power law than in August, 1912?

A. I cannot say that definitely because the degree of agreement of the August experiments were subject to a good deal of experimental error, that is, the data do not fix the exponent closer than between 1.5 and possibly 2.0.

No, the conclusion is based more on my knowledge of the conditions, that resulted from the experiment 317 where we had rather similar conditions. In that experiment different amounts of nitrogen were placed in the bulb and I have studied carefully the effects that were produced by these different pressures of nitrogen on the departures from the 3/2 power law or the exponent to which these pressures of nitrogen produced that ionization sufficient to modify the space charge effect, and from those results I believe that 0.3 or 0.4 of a micron of nitrogen at 250 volts would have produced a perceptible, perhaps five or ten per cent. increase in the current over what it would have been in the highest vacuum at these voltages.

I do not find any evidence, I think, without having investigated that point particularly or more definitely, that the data of November 19th agrees more accurately with the 3/2 power law. (After inspecting notes.) In this case the data on the exponent are somewhat more accurately determined than they were or can be determined from the August experiments. I rather believe that the November experiments fix the value of that exponent closer to the 3/2 power law than you would get with pressure as high as 0.4 of a micron. The difference, however, I think is relatively insignificant.

My real belief that the pressures in the November 19th experiments were much lower than 0.3 of a micron is based on my knowledge of the effectiveness of the clean-up process when relatively large amounts of tungsten are evaporated.

XQ. 607. In the original specification filed with your application on which Patent No. 1 was issued, you said on page 4: "I have found that deleterious gases may be removed by electron bombardment even at a low temperature." Is that correct?

A. I believe there was such a statement in the original specification, but I do not believe that the fact described there is true. I think that that statement was based on something which later on I found was not true. In other words, I do not believe that gases can be removed from metals effectively by electron bombardment without heating the metals.

XQ. 608. At another place in the specification, that is at page 6, I suppose the same answer applies: "However, heat alone will not remove all the gas liberated by the electron discharge, but this gas is driven out even at ordinary temperatures by the discharge itself." Is that right or wrong?

A. Do you mean the facts stated there or whether it is in the specification?

XQ. 609. That is what I mean. First, is that correctly quoted and second is it now true?

A. It is correctly quoted.

The statement consists of two parts and the first one has a certain element of truth, or has considerable truth in it and the second one has very little. Take the second statement. It says: "This gas is driven out even at ordinary temperatures by the discharge itself." I do not believe that an electron discharge by itself will drive gases out of metal electrodes unless the intensity of that discharge is sufficient to heat the electrodes. However, the passage of the discharge itself even without heating the device is an important element or at least a useful element in the exhaustion of tubes in this way, that if an electron discharge is passed through the tube a certain amount of positive ionization occurs. The positive ions formed bombard the glass and if the pump is working quickly and rapidly some of that gas which is knocked off the walls will be removed by the pump. So that the passage of the discharge while the device is on the pump is a factor in freeing the walls of gas.

In regard to the first statement, the first statement is: "Heat alone will not remove all the gas liberated by the electron discharge." For high voltage discharges that is quite important; that is, to get the best results it is not sufficient—and by high voltages I mean thousands of volts—it is not usually sufficient merely to heat the electrodes. It is very important to apply to the tube high voltages in order to subject the glass to all the positive ion bombardments that it is going to receive in practice and more besides so as to free the glass from deleterious gases.

XQ. 610. This matter of positive ion bombardment of the glass is not pointed out in the specification, is it?

A. The theory of those things was not understood at that time at all.

XQ. 611. And again near the bottom of page 6 it says that "heating . . . may be omitted when the devices are not heated during normal operation." Is that true?

A. No.

XQ. 612. Of course, you believed these statements were true when you executed the oath to this application?

A. Yes.

XQ. 613. Did you still believe them to be true when you executed the supplemental oath on June 24, 1914, that appears on page 54 of the Interference record?

A. No, I do not think I believed it at that time.

XQ. 614. You notice that this oath refers to the apparatus as disclosed in the specification and claimed in certain claims. Did you make a mistake in executing that oath?

A. I really do not understand what all this means now and I do not believe I did at that time as to what is covered by Claims 6 to 9.

XQ. 615. I am referring more particularly to the annexed specification.

A. I do not know whether that is the specification as originally filed or as amended. I am not very familiar with the legal practices in these patent matters. I usually leave such matters to the Patent Department.

XQ. 616. You mean you execute affidavits without checking them over and the papers that they refer to?

A. I read them over but I may not realize the full legal significance or the full significance of everything in them.

XQ. 617. And for the supplemental oath that you executed on March 10, 1916, shown on page 67 of the Interference record your answer would be the same?

A. I suppose in signing these statements my attention was called entirely to changes that were contemplated at the time this statement was made, that is, certain changes in the—I do not remember anything about these particular supplemental oaths. I can hardly tell what I had in mind at that time but I do not suppose at that time I read over the whole original specification. What this supplemental oath seems to say is that the apparatus as disclosed in the specification and claimed in Claims 1 to 18, are submitted by the accompanying amendment and constitute a part of this invention.

> "Also that it was not used or known before my invention was patented."

Now, all of those statements seem to me not to relate at all to any statements in the specification regarding whether or not it is possible to free a gas from metal by cold bombardment; that it does not seem to me to have anything to do with Claims 1 to 18, or have anything to do with whether the apparatus disclosed in the specification was new or old. So that I do not believe that in signing this thing that I had the slightest thought in my mind of any such subjects or questions as to whether or not the specification contained a statement that cold bombardment would or would not free an electrode from gas. The whole object of the supplemental oath, as I understood it, and the statements in it, have no reference to such minor points as theories of method of exhaust. The device and the novelty of the device, those seem to me to be the important matters.

XQ. 618. But among those claims 1 to 18, which were covered by your supplemental oath, executed on March 10, 1916, was one which then read as follows:

> "The process"——

A. When do you mean by "then"?

XQ. 619. It had been amended previously to that, and it stayed in the case at the date of your supplemental oath, as follows:

> "The process of removing ionizable gas from an anode of an electron discharge device which consists in subjecting said anode to prolonged electron bombardment with an energy input below the value necessary to appreciably heat said anode an impressed voltage below the value at which considerable gas ionization occurs, and coincidentally removing the gas thereby disengaged."

So it seems to me perfectly clear that your affidavit referred to that claim and others of that sort, and all I am asking you now is whether you made a mistake when you signed that affidavit, or not?

A. I really am not at all clear as to what was really in the affidavit that I signed or claimed. I have no recollection of the matter at all at present.

XQ. 620. But if that claim was in there then, then your affidavit was wrong, was it not?

A. I do not know. I do not get the significance of the affidavit and the claim. I mean you say that there is a certain claim. I do not know at present what the relation is between the affidavit and the claim. I am not at all clear in the matter.

XQ. 621. I think I can make that clear. The affidavit reads that Irving Langmuir

> "deposes and says that the apparatus as disclosed in the specification and claimed in Claims 1 to 18, inclusive, . . . constitutes a part of his

> invention, was invented before he filed his original application, above identified, for such invention, was not known or used before his invention."

and so on. You were making an affidavit to that very claim that I read just then, according to the wording of this oath, and I want to know whether you knew what you were doing, and whether that was correct?

A. Was this in 1916?

XQ. 622. Yes.

A. Was that claim first introduced at that time, or when was it first introduced? Was it part of the original specification?

XQ. 623. A claim was part of the original specification which a few months later was amended to read as I showed you. This paper that I hand you gives the full history of the thing (handing paper)?

A. This is what—Claim 10?

XQ. 624. It was originally Claim 1.

A. In the original specification as filed in 1913? What you have in black ink here was Claim 1?

XQ. 625. Right. To keep the record clear, I think I had better read Claim 1.

The Court: May I make this inquiry, Mr. Richmond? It seems to me that possibly you have gotten the fact that you want from the witness when he tells you that he learned at least probably before 1914, and surely before 1916, of the incorrectness of the theory stated in the original specification. Now then, I am wondering whether or not your immediate question is not asking the witness to construe the affidavit, which is a judicial function, and not one required of the witness, and whether you have not gone as far in this matter as it is necessary for you to go, even from your point of view?

Mr. Richmond: I think that is the correct position. I am ready to withdraw the question.

THE COURT: Very well.

XQ. 626. Having made that mistake in your original application——

MR. RICHMOND: Mr. Smart, will you read the first part of the question? (Question repeated as recorded.)

XQ. 627. Having made that mistake in your original application by stating that the bombardment without heating might be sufficient, and having become aware that that was a mistaken view, what steps did you take to correct it?

A. I have no precise recollection of what I did. I believe that I called the attention of somebody in the Patent Department to it.

XQ. 628. When?

A. I do not know when, or to whom. That is, the fact that our Patent Department did make subsequent changes, and that I had changed my idea, makes me believe now that I called it to the attention of somebody in our Patent Department, but I have no further recollection of it.

XQ. 628a. Is your recollection as to the date of when you called their attention to it refreshed by the fact that the record shows that those statements in the specification and the claims carrying the same statements were never cancelled until July 30th, 1925?

MR. DAVIS: If your Honor please, this raises the point which we discussed a day or two ago, and while Mr. Richmond's views and mine are not quite the same, I think it proper to state my view. My understanding is—I was an Examiner once myself in the Patent Office, so that I go back to those days some years ago—my understanding is that when an Interference is declared, the papers pass out of the custody and control of the Primary Examiner, in exactly the same sense that the papers on an appeal would pass out of your Honor's custody when the case was certified to the Court of Appeals, and a transcript filed there; even more so, because the actual physical papers are taken away, and there is nothing remaining in the Examiner's room, except such notes as the Examiner may have made to remind him that there was such an application there. They are then put in the jurisdiction of the Examiner of Interferences, and there they remain except that they are taken away from him, of course, on appeal.

Now, while it is physically possible to file a paper with the Examiner at any time during the progress of the Interference, it is about the same thing as though a paper were filed here in this court with reference to a case which was in the Court of Appeals of the Third Circuit on Appeal. I should think your Honor would regard that as an impropriety in any ordinary case. I do not know the practice, but I certainly regard it as an impropriety in the Patent Office unless there is specific reason for it. It causes the Primary Examiner to go up to the Interference Division, and he has to get an Order of the Commissioner, as I understand it, before he can take any action, that is, get his jurisdiction restored by the supervisory power of the Commissioner, and I may be entirely in error as to what is proper to be done, but my understanding is you make notes through the progress of the Interference, and when the Interference is over, you do it.

The Court: So far as I know here, the only time any application has been made while a case has been pending in the Court of Appeals of this Circuit, has been made only—I think an application has been made, but I think the applicant has been sent to the Court of Appeals to make his aplication there for leave to make the application here.

Mr. Davis: Yes, you can do that in the Patent Office.

The Court: I beg your pardon?

Mr. Davis: Yes, you can do that in the Patent Office.

The Court: But I do not remember what this question was, so let me see if you are getting away from the fact—read the question. (Question repeated as recorded.) I think that question can be answered, because I think that calls for a fact; it is not when the application was made, but when Dr. Langmuir, the witness, communicated the fact he had made a mistake to the Patent Department of the General Electric Company, as I understand it, is it not?

Mr. Richmond: Yes, your Honor.

The Court: So what they did seems to me another matter, so I will overrule the objection on that ground. Read the question.

(Question repeated.)

A. I believe that I called the attention of the Patent Department to these matters, most probably in 1913, certainly the date of 1925 that you suggest does not bring any recollection of the matter to my mind. In fact, I do not remember having known that the changes were made in 1925.

Mr. Richmond: I would like to add just a word, your Honor, to the discussion a moment ago. I am quite sure that I remember instances of giving notice on the record in the Interference proceeding of an intention to amend at the first opportunity, a very simple thing to do; and it seems to me that when an error is discovered, that is a very obvious and a very appropriate procedure.

The Court: I am wondering how I can take judicial notice of that practice any way. That is, assume that you are right, assume for a moment that you are right, and assume for a moment, on the other hand, that Mr. Davis is right. Can I get the proper practice or procedure from judicial notice? Or must I have proof of it? Or can I take judicial notice—I assume that I can, of the rules and regulations of the Patent Office, but if it is not expressly laid down in any rule, then would it not be an inference from the practice—not the practice, but the law, it would not be law so much as practice probably——

Mr. Davis: If your Honor please, I suppose that Mr. Richmond and we could agree on that; that is, if Mr. Richmond agrees, as I am sure he does, with my statement which I just made, I can agree that anybody has the power [illegible] dictate such notice as he suggests on the Interference record any time he wants to.

Mr. Lunt: If your Honor please, I would like to say that I too was an Examiner in the Patent Office, and familiar with the practice, and I never heard of any such practice as this.

Mr. Davis: You are not a witness.

The Court: My difficulty is this—as counsel I cannot hear you on the practice in the Patent Office unless I can take judicial notice of it. I think there is no difficulty, because I think there is really no substantial disagreement between you on this, namely, that when an Interference is declared, that takes the whole jurisdiction of the case over to another department, to the Examiner of Interferences it is called, is it not?

Mr. Richmond: The whole thing is under the jurisdiction of the Commissioner. All communications are always addressed to him.

THE COURT: Surely. I see.

MR. DARBY: The same relation of the District Court and the Court of Appeals in no sense exists in the Patent Office.

MR. HAIGHT: May I suggest this, in order to clear up and I hope it will not complicate. I understand Mr. Davis' proposition is that the amendment could not have been made after the Interference was declared. It seems to me that that does not affect the case at all because the Interference was not declared until 1916, and Dr. Langmuir says he discovered this defect in 1913 or 1914, so that they had two years to make the amendment if they had been mindful to do so, whatever effect it may have had on the case.

THE COURT: The statute having begun to run it continued to run.

MR. HAIGHT: Yes, sir. I do not think it makes any difference what the practice in the Patent Office is.

THE COURT: I see.

By MR. RICHMOND:

XQ. 629. I understood you to state in your direct deposition that in 1912 you understood that heating of an anode to 400 degrees was entirely inadequate; is that correct?

A. I think that is true. I certainly was in the practice of heating anodes to 2400 degrees and more and attached a great deal of importance to this heating of the anodes. I had had no experience with heating large metal plates used as anodes.

XQ. 630. So that this view that crept into the patent application when it was filed in October, 1913, arose in your mind after that?

A. Yes, it arose during February, 1913.

XQ. 631. This same error appears in the patent that was issued to you as reissue 15,278 on an application filed originally July 23, 1918, and for which the reissue application was filed on April 23, 1919. I direct your attention especially to page 2, lines 67 and 68 of the specification where it says: "But heating is not essential." Is that correct?

MR. RICHMOND: I will withdraw the question. I see my mistake.

XQ. 632. When did you say it was that you discovered this error or did you say?

A. I have no definite recollection of having as you say discovered an error. In February, 1913, I remember distinctly having had a theory, based upon two or three different things, that electron bombardment would remove gases from the very surface of the metal electrodes. I did not think that it would remove gases from the deeper layers inside of the metal but I thought it would remove gases from the surface layers of metal electrodes and I believed that the gas in metal electrodes that was in the interior of the electrodes would come out when those were heated during operation and therefore I concluded that if an electrode was to be run at low temperature with very little energy the gas in the interior would not be able to come out and it would be merely necessary to clean the surface so as to make it free from gas and that this could be accomplished by pure electron bombardment without necessarily heating it.

Later on in 1913 we made up tubes with plate shaped anodes. The first three-electrode tubes that were made beginning in March, 1913, had anodes that were heated by the passage of current through them because that was a sure way of getting good results and as a matter of fact, we continued that process in making small audions for 250 volts well into 1914, but we also in 1913 made audions, and these "hot cathode relays" that were used for higher voltages, with plate shaped anodes. When we made these we very soon came to realize that it was very important to heat the electrodes to very high temperatures during the exhaust and it became our practice to heat them to a white heat and used tungsten or molybdenum plates and heated them by high voltages and high currents until they were very hot.

So that this idea of bombarding cold was not used in practice and my attention went off it and I practically forgot it. I believe in discussion with men in the Patent Department I told them that we used high voltage discharges but I do not remember ever having told them specifically to take those statements out of the patent.

XQ. 633. But when was it, what I want to know is when it was that you abandoned this incorrect theory?

A. I do not remember. The theory sort of petered out and died gradually. I do not think I ever made a definite—I do not think the time ever came when I said, "Now, I will abandon this theory. The theory is wrong." I think the theory died a sort of natural death in my mind and I think that in my conferences with the Patent Department men I probably expressed increasing doubt as to the effectiveness of that method.

XQ. 634. Now, in my effort a moment ago to frame a question I got some dates mixed and opposing counsel kindly directed attention to it and I withdrew the question. I will try again. I direct your attention to Langmuir reissue patent 15,278, filed originally on an application dated October 16, 1913, and reissued on an application filed April 23, 1919. This same error appears in the specification of this reissue patent, does it? Please refer particularly to page 2, lines 67 and 68 where it says: "But heating is not essential."

MR. RICHMOND: This patent has already been offered.

A. I think this statement is incorrect and that I overlooked it in reading the specification. I really do not remember now whether I reread the specification in 1919 or not. I suppose I probably considered it was the same specification that I had originally filed and did not remember that statement in it.

XQ. 635. I understood you to testify that in the literature up to but not including 1912, there were quite a large number of papers being published which expressed great scepticism or doubt as to the possibility of getting electrons out of the metal in a perfect vacuum. Can you remember the names of the authors of these papers and mention them to us?

A. They are referred to in the various papers that are published. Some of them are mentioned in my *Physical Review* article published in 1913, and others are mentioned, I think, in my 1915 article that was read before the American Institute of Radio Engineers.

Mr. Richmond: Mr. Lunt, those have been put in evidence, have they?

Mr. Lunt: I do not remember about that.

Mr. Richmond: They are in the Interference record?

Mr. Lunt: Yes.

Mr. Richmond: That is all right.

A. (Continued): There are probably a few others. I do not recall them at the present time.

The theory that you speak of was that electrons were emitted only as a result of some secondary effect tied up with the presence of gas. Some people referred to that as a chemical theory but so far as I know practically all of those people that referred to that as a chemical theory were physicists and I believe the state of affairs was about this——

Mr. Richmond: I ask that the last part of the answer be stricken out as not responsive.

THE COURT: Strike out all the answer after the point that he does not recall the others at this time.

By MR. RICHMOND:

XQ. 636. Is it not a fact that even including the year 1912, Soddy and Pring and Parker were the only ones expressing doubt of the Richardson theory of electron emission?

A. I do not remember exactly at present the dates of the other publications that are referred to. My impression is that some of the others were in 1912. There were some papers by Fredenhagen and by Hallwachs and there is a paper by Marsh and possibly others and it is my impression that these were in 1912 or before. I believe the paper by Marsh is referred to in the transcript. All of these references are discussed in the transcript record on the motion.

XQ. 637. I believe you have the *Physical Review* paper of December, 1913, there, and here is a copy of the radio engineers paper that you referred to. Now, I would like to get a complete list of those names from you and verify the ones that you have mentioned. I do not want them after 1912.

THE COURT: You want 1912 excluded or included?

MR. RICHMOND: Included.

A. May I refer to the transcript record to find out about that paper by Marsh?

XQ. 638. Yes.

A. In my paper before the Institute of Radio Engineers I find that the references I made, that is, limiting myself to those before 1913, were Soddy in 1908, Fredenhagen in 1912, Pring and Parker in 1912, and then in the transcript record 1374 up to 1376, there is a discussion of two papers by Sidney Marsh, one in his Doctor's Thesis published at the University of

Göttingen in 1909 and part of which was reprinted or was the basis of a new paper published in the *Annalen der Physik* in 1910. Those are the only references that I find in my paper or in that record up and including 1912.

XQ. 639. I believe that you have said that you read a paper at the meeting of the Physical Society on October 18, 1913. About how long did it take you to read that paper, how long were you speaking on that occasion?

A. The paper itself was probably ten or fifteen minutes and there was probably twenty minutes of discussion.

XQ. 640. Discussion by others and yourself?

A. Yes.

XQ. 641. Then what you read was not the paper that was published in the *Physical Review* in December, 1913, because that would have taken far longer?

A. I did not give all of the data that are in that paper as published in December, but I summarized the main points and illustrated them with lantern slides.

XQ. 642. And it is your practice when you do what they call reading a paper before the society to speak extemporaneously, is it not?

A. Yes, but with very carefully prepared notes and lantern slides illustrating my points.

XQ. 643. And I show you first an abstract of a paper presented at the New York meeting of the Physical Society, October 18, 1913, by yourself, and ask you if you prepared that abstract (handing paper)?

A. Yes, I prepared the abstract.

XQ. 644. And of course you intended to make that abstract correspond to what you said, did you not?

A. I do not think so particularly. I made the abstract to cover the subject matter but I do not think I had any particular intention to make it cover precisely what I said. That is, of course I said in ten or fifteen minutes a great deal more than is contained in that abstract, and when you have the problem of writing down a short abstract of that kind, and have to make it readable as it stands, you have a great many other factors coming in, in determining what you say, when you have ten or fifteen minutes to present the paper.

XQ. 645. But of course, you tried to make the abstract representative of what you said, to make it truly an abstract of what you said?

A. I do not know that I particularly tried to do that. I tried to make it just as though it were a separate paper of very short length, dealing with the general subject, and giving information which I think would be particularly interesting to the readers of the *Physical Review.* I probably said in my paper all the things that are contained in the abstract, but I said a great deal more besides, and I do not think there is anything in the abstract which was not covered by what I said.

XQ. 646. Well, what was the purpose or object of preparing and publishing this abstract?

A. Well, it was the custom at that time for those who read papers before the American Physical Society, to publish very short abstracts in connection with those papers, and I wished to avail myself of that privilege at that time by publishing a short account of the work that I had been doing. Of course, the Physical Society, is a society of pure scientists, interested in physics, primarily.

XQ. 647. And this abstract was prepared for the purpose that you have just stated?

A. Yes.

Mr. Richmond: I ask to have this marked for identification as "Abstract of Paper presented by Dr. Langmuir on October 18, 1913, published in *Physical Review* for November, 1913."

(Received and marked "Defendant's Exhibit M for Identification.")

XQ. 648. That abstract gives two 3/2 power law equations, and you worked out some of the mathematics for those on the blackboard at the time you made this presentation, did you?

A. I do not believe I worked that out. I think I probably stated the results.

XQ. 649. And you did not give any of the mathematical steps leading to those results.

A. I do not remember at all whether I did or I did not. I think it is rather quite improbable that I did, because it is not my custom as a rule, in lectures, to give mathematical derivations. Most people find them very uninteresting to listen to.

Mr. Richmond: Cross-examination closed.

Mr. Haight: Now, Mr. Darby.

Mr. Richmond: Excuse me, my part of it.

Mr. Darby: I will be very brief.

Cross-Examination.

By Mr. Darby:

XQ. 651. As I understand it, Dr. Langmuir, referring to electron bombardment of, let us say, a plate electrode to free it from gas, it is the heat that frees the electrode from gas, is it not?

A. Yes.

XQ. 652. And one way of imparting or giving to the electrode the necessary heat, is by bombarding it with electrons?

A. Yes.

XQ. 653. Now, if you bombard a plate electrode for a given period of time, say at 100 volts, you can operate that device, assuming it is a three-electrode device, at eighty volts thereafter, without having the plate electrode give off gas, can not you?

A. No.

XQ. 654. You can not?

A. No. Not in general, no.

XQ. 655. What is that?

A. Not in general.

XQ. 656. Is it not a fact that after you bombard a plate electrode for a certain necessary length of time at one voltage, that that electrode will not give off gas when operated normally below that voltage?

A. No. There is no relationship.

XQ. 657. There is no relationship between the——

A. Between the voltages, no.

XQ. 657a. Is there no relationship between the voltages and the heat?

A. No, not necessarily.

XQ. 658. Then as I understand you, I could operate, or I could bombard a plate electrode at a high voltage for a short length of time, and get a certain amount of heat thereby, or I could bombard a considerably longer length of time at a lower voltage, and get the same amount of heat; is that right?

A. Not necessarily.

XQ. 659. It is possible?

A. Why—you have not mentioned anything about current. The bombardment does not depend on voltage; it depends on the product of voltage and current.

XQ. 660. All right. Then, suppose we have a given current value, and a given period of time. That is, the remaining constant, if I bombard at 100 volts, will I thereafter be able to employ that vacuum tube at the same or smaller amount of current under 100 volts?

A. Not usually. At some voltage under 100 possibly, depending upon whether you have used a sufficient amount of current and voltage. That is, in order to tell whether or not the electrode has been sufficiently freed from gas under any given conditions, there are many factors that are more important than mere voltage and time. Thus, the amount of the energy, the actual temperature to which the electrode is raised are more important factors than even voltage or current.

XQ. 661. That is what I understand. And in the ordinary practice of manufacturing the so-called high vacuum tubes today, do you bombard the plate electrodes?

A. Yes.

XQ. 662. Electron bombardment in all types of tubes that you make?

A. No, I do not think so—most of them.

XQ. 663. What do you employ to heat the electrodes outside of the bombardment?

A. The most effective method used today is the high frequency induction devices by which the electrodes can be heated red hot by means of a high frequency alternating field applied from outside the tube.

By Mr. Darby:

XQ. 664. And that high frequency field does not heat the glass vessel, does it?

A. Only in so far as it becomes heated by the radiation from the electrodes.

XQ. 665. By conduction?

A. By radiation.

XQ. 666. Do you likewise heat the plate; to your knowledge, do they heat the plate electrodes to free them from gas by conduction through gas in the tube itself?

A. No.

XQ. 667. You do not know of anybody that employs that process?

A. No.

XQ. 668. You do not know of a process being manufactured today manufacturing vacuum tubes where they employ the gas that is in the tubes to conduct heat to the plate electrodes?

A. No.

XQ. 669. To get them hot?

A. No.

XQ. 670. Do you see any reason why that could not be done?

A. I do not see—I can not imagine why it should be done. It seems to me a very ineffective method.

XQ. 671. That was not my question. Do you see any reason why it could not be done?

A. Why what could not be done?

XQ. 672. Applying heat to the outside of a vessel and employing the gas inside of the vessel to conduct that heat to the plate electrode to free it from gas, or at least partially free it from gas?

A. I do not see that the gas would serve any useful function at all, nor do I see how the result obtained by it——

XQ. 673. That does not answer my question.

Mr. Davis: Let the witness answer.

XQ. 674. To avoid any possible dispute, Doctor, will you answer my question first, and make any explanation you desire?

A. I do not think the question can be answered without qualification. May I have the question read?

XQ. 675. Answer it and qualify it. I do not want to cut off your qualification.

A. Read the question. (Previous part of the record repeated by the stenographer as recorded.)

Mr. Davis: I submit, if your Honor please, that he is entitled to answer that question and was answering it while he was interrupted.

The Court: Mr. Darby's objection was the technical one that he did not answer the question before explaining it. He is entitled to a categorical answer, and followed by the explanation that he did not give, so I think he is entitled to that right. You may answer.

The Witness: My difficulty is that it seems to me there are several things you ask that are more or less incompatible to one another.

Mr. Darby: All right. We will drop that for a minute then.

XQ. 676. Let me ask you this: If an electrode has been heated to 400 degrees C., to free it from gas, can that electrode thereafter be employed in normal operation, where its heat does not exceed 80 degrees C., let us say?

A. In general, not; it can not be. That is, it can be employed but I mean to say—of course, you can employ it, but you do not get a useful result.

XQ. 677. You answered before I concluded my question, Dr. Langmuir. My question is, if an electrode, a plate electrode, a three-electrode device has been heated to the proper degree of heat, which I understand from you is in excess of 400 degrees C., is that correct to free it from gas—an excess of 400 degrees C. will free a plate electrode of gas if it is connected at that heat a sufficient length of time?

A. Certainly not.

XQ. 678. What degree of heat is necessary?

A. A good, bright red heat.

XQ. 679. Which is about?

A. 700 or 800 or 900 degrees.

XQ. 680. I consider that to be an excess of 400 degrees C. If we heat the plate electrode to 700 or 800 or 900 degrees C., sufficient to free it from gas, and keep the heat there long enough, and I employ that electrode as the anode of a three-electrode vacuum tube in normal operation, it will not thereafter give up gas, will it?

A. I think it will give up some.

XQ. 681. But not enough to cause harmful ionization?

A. It depends on the conditions.

XQ. 682. What is the normal heat of a plate electrode in operation on a three-electrode tube?

A. It depends upon the size of the tube and the heat coming from the cathode.

XQ. 683. Take your standard UV-201?

A. I hardly know definitely, but it is probably 300 or 400 degrees C.

XQ. 684. Well, now, does that plate electrode, when it is heated up to three or four hundred degrees C. in normal use give off sufficient gas to cause harmful ionization effect in the operation of the tube?

A. Not if it has been properly treated for gas beforehand, otherwise it does.

XQ. 685. Therefore, if you once heat the electrode, getting back to my main question now, to the necessary degree of heat and maintain it at that heat sufficiently long enough to free it from gas, when you thereafter use that electrode as the anode of a three-electrode device which in normal operation does not become heated to anywhere near the degree of heat to which it was initially heated to free it from gas, that anode will not thereafter liberate sufficient gas to cause harmful ionization, ignoring all other parts of the tube for the purpose of this question. Do you agree to that?

A. It may or it may not. The point that I want to bring out is that you need a very great factor of safety for the reason that the tube is to be operated——

XQ. 686. I think, Dr. Langmuir, you have answered my question. When you heat you can of course, and in fact in practice you do heat the plate electrode while there is some gas in the tube?

A. During exhaust, do you mean?

XQ. 687. Yes.

A. Yes, there is always some gas in the tube.

XQ. 688. And the heat of the electrode is brought up gradually, it is not instantaneously applied, referring to electron bombardment?

A. That is correct.

XQ. 689. And while it is gradually being brought up to a high temperature it oxidizes to some extent, does it not, the surface of the anode?

A. No, I do not think so.

XQ. 690. You do not consider that it is possible for the surface of that anode to oxidize because of some oxygen that is in the tube?

A. No, not in any reasonably good exhaust treatment. The heated filament would consume oxygen sufficiently to prevent that action. But as a matter of fact, with any reasonably good pump the pump will remove the oxygen.

XQ. 691. When you heat the anode does it change its color or appearance?

A. Not as a rule.

XQ. 692. If it does change its color or appearance what causes it?

A. I am not familiar with the phenomenon of anodes changing color during exhaust.

XQ. 693. If you raise a metal to a substantial heat it changes its color in air?

A. Yes, some metals.

XQ. 694. That would be true of nickel, would it not?

A. Only heat at a pretty high temperature.

XQ. 695. Only if you heat it to a pretty high temperature?

A. Nickel stays bright and clear until heated to a pretty high temperature.

XQ. 696. I show you the original DeForest audion which was left with the Western Electric Company by Dr. DeForest in 1912, marked Defendant's Exhibit

139 here, and I ask you to look at the plate electrodes in that tube. Do they show discoloration?

A. Yes. I notice that the plates are soldered to the leads, which means that they have been heated in the air before being mounted in the tube and presumably oxidized.

XQ. 697. Can you give an idea as to what kind of solder that is employed there?

A. Not very well. It does not look like ordinary tin lead solder.

XQ. 698. Would it in your opinion be silver solder?

A. I do not think so. Silver solder usually has a yellower color than that. I do not know very much about the solder from looking at it. It is probably not made of lead and tin. That is about all I can say.

XQ. 699. Now let us consider a moment a vacuum tube that has mercury vapor in it. The mercury vapor will in any circumstances readily form an amalgam with a great number of metals, will it not? In other words, mercury amalgamates with silver, gold, platinum, copper, very readily?

A. Mercury amalgamates with silver. Not I believe with platinum. It does readily amalgamate with gold. It does not usually amalgamate with copper unless the copper is chemically cleaned so as to remove all traces of oxid.

XQ. 700. And if we are working with a mercury pump and evacuating an audion tube and the audion tube is not heated while it is being evacuated, the mercury vapor tension, unless some means are taken to keep the mercury out of the tube, such as by charcoal and liquid air, would be very high when that tube is sealed off, would it not?

A. It would be a few microns.

XQ. 701. Which is very high compared to the pressure in a so-called high vacuum tube?

A. Mercury vapor is particularly effective in forming——

XQ. 702. Will you answer my question first, then?

A. It may or may not be. I cannot answer it without qualification.

XQ. 703. If I heat the vacuum tube while it is being evacuated by the mercury pump, will that make any difference in the mercury vapor that is in the tube after it is cooled and sealed off?

A. I suppose it would make some.

XQ. 704. In which direction? There would be less mercury vapor in the tube?

A. Somewhat less mercury vapor.

XQ. 705. Now, if you employ a thoriated tungsten filament let us say—first let me ask you this question. Can you evacuate a tube without the employment of a vaporizable reagent such as potassium or magnesium or anything of that nature, can you evacuate a tube sufficiently high so that you can use a thoriated tungsten filament in it?

A. Yes.

XQ. 706. And the thoriated tungsten filament if properly activated, aged, will emit electrons and operate in a three-electrode tube?

A. I suppose when you speak about emission from a thoriated tungsten filament you refer to emission at a low temperature which is made possible only by the thoriated filament.

XQ. 707. I was not confined to temperatures or anything of that kind. My inquiry is this. Can you construct a three-electrode vacuum tube that you can turn over to me and I could use in a radio receiving set, let us say, employing a thoriated tungsten filament where the necessary degree of vacuum or where the degree of the vacuum of the device you turned over to me was turned out without the employment of any vaporizable reagent such as potassium and magnesium?

A. It seems to me very important to understand definitely that a thoriated tungsten filament can always be operated as a tungsten filament without any beneficial results of the thorium.

XQ. 708. I want to get the beneficial results of the thorium?

A. That means that you want to operate at low temperatures.

XQ. 709. I want to get the beneficial results of the thorium including everything that you have in your mind.

A. The full benefits of the use of thorium.

XQ. 710. I want the benefits of thorium.

A. The appreciable benefits?

XQ. 711. Any benefits, anything that makes it better than the pure tungsten would be?

A. With that in mind, may I have the question again?

(XQ. 707 was repeated by the stenographer.)

A. I think I can do so, in fact I am sure.

XQ. 712. In other words, the benefits to be derived by using the thorium contained on a thoriated tungsten filament in a high vacuum tube are not in any sense dependent upon the employment of a vaporizable reagent; is that correct?

A. The vaporizable reagent is of very great use.

XQ. 713. I understand that, but my question is that it was not entirely dependent?

A. It is not absolutely essential to use those reagents that you spoke of.

XQ. 714. And as a matter of fact, the reagents are employed to keep the filament from oxidizing and water vapor or any oxygen or other gas that may become evolved in the tube irrespective of their source, is that correct?

A. Not so much to prevent the filament from oxidizing as to prevent the thorium film on the filament from oxidizing.

XQ. 715. And in other words, they would perform that same function, for example, with other types of filaments, would they not? Strike that out. Let us take the case of magnesium. You employ magnesium to take up water vapor or any other gases that might be evolved from any of the electrodes within the tube; is that correct, or from the walls of the tube?

A. More than that, but that is one of the things for which the magnesium is used.

XQ. 716. And the same is true of potassium, only magnesium goes much further than potassium; is that correct?

A. Except the second statement. I do not think magnesium goes any further than the potassium.

XQ. 717. But let me withdraw the second statement. The same thing is true of the potassium?

A. The potassium does those things and may do other things besides.

XQ. 718. And they would perform those functions, both magnesium and potassium would perform those functions irrespective of any particular type of filament that you employed, would they not?

A. The functions that I am speaking about are the prevention of oxidation of the thorium film.

XQ. 719. I am talking about the functions that I was speaking about a minute ago which were to take up any gases which may be evolved from any of the electrodes from the interior construction of the tube, those materials would perform those functions irrespective of what type of filament was employed?

A. You broaden your question into any gases coming from any electrode. That is not what you were talking about before. You are talking about water vapor and oxygen containing gases.

XQ. 720. Confine it to water vapor and oxygen containing gases.

A. Then it is true that the function of magnesium or potassium in removing those gases would not be dependent on the material of the filament.

XQ. 721. Now, in preventing oxidation of thorium, for example, or the surface film of thorium as you call it, by means of potassium, you prevent that by having the potassium take up or get the oxygen containing gases as soon as they are evolved from any portion of the interior construction of the tube including the electrodes; is that correct?

A. Yes.

XQ. 722. So that in preventing the oxidizing of the filament you do that in that manner by having the potassium or magnesium or whatever else is employed combine with any gases that are given off from any part of the interior of the tube?

A. By any gases again you are referring to oxygen bearing gases.

XQ. 723. Yes.

A. Yes.

XQ. 724. And as I understand you, you never possessed a three-electrode audion until some time in February, 1913?

A. Not the DeForest audion. The tube that we had——

XQ. 725. I am referring to a three-electrode vacuum tube consisting of a filament and a plate with a grid electrode interposed between them?

A. We had a three-electrode tube on November 19th, and to some extent that was actually used as an audion.

XQ. 726. You consider that to be a three-electrode tube of the DeForest audion type?

A. I think the DeForest audion is broad enough to include such a tube.

XQ. 727. But in February, 1913, was the first time you actually possessed a filament grid plate audion?

A. Yes.

XQ. 728. Is that the first time that you had ever seen one?

A. Yes.

XQ. 729. Had you read anything about it prior to that time that you recall?

A. I believe I did in January after Mr. Alexanderson had told me about the audion. I think I looked up DeForest article at that time. January, 1913.

XQ. 730. In your 1915 paper in the proceedings of the Institute of Radio Engineers you made this statement, did you not:

> "My active interest in thermionic currents began in connection with some experiments on electrical discharges occurring within tungsten lamps."

And then you made reference to Richardson's data and then you stated this:

> "It was known that the vacuum in a tungsten lamp is extremely high, and measurements indicated that in well exhausted lamps after one hundred hours life the pressure was probably less than one-millionth of a millimeter of mercury."

That is correct, is it not?

A. Yes.

XQ. 731. That is what you stated in your paper?

A. Yes.

XQ. 732. What is one-millionth of a millimeter expressed in terms of microns?

A. One one-thousandth of a micron, 0.001 micron.

XQ. 733. One one-thousandth of a micron?

A. Yes.

XQ. 734. And then your paper proceeded to state:

> *"Taking these two facts into account, the very existence of a tungsten lamp seems strong evidence that thermionic currents in high vacuum must be very small, if not entirely absent."

Is that correct?

A. Yes.

XQ. 735. So that you recognized at the time you started your investigations on the thermionic vacuum tube, that the very existence of a tungsten lamp meant the existence of a vacuum as high as one one-thousandths of a micron—was that the correct figure?

A. Yes.

XQ. 736. One one-thousandth of a micron, is that correct?

A. No. I did not get that question. Will you please read it? (Question repeated as recorded.) I do not think there is really a question there.

XQ. 737. I will re-put it. Then you knew at the time you began your experiments which led up to the work concerning which you have testified, that the very existence of a tungsten lamp which had been in operation one hundred hours, meant the existence of a vacuum equal to one one-thousandths of a micron?

A. No, not exactly.

XQ. 738. All right.

A. Shall I go on? Do you want me to?

XQ. 738a. You do not have to on my account, if it is your impression——

A. I mean the conclusions are a little different from that. First, I say where any vacuum as good as that existed in a tungsten lamp, but that was not concluded from the existence of the tungsten lamp, that conclusion was drawn from measurements that we had made pressures in lamps; the existence of the tungsten lamp, the very existence of the tungsten lamp, proved that thermionic currents under those conditions were smaller, but did not themselves prove that the vacuum was high.

XQ. 739. Did it not prove that the very presence of tungsten as a filament in an incandescent lamp, due to its operation, would automatically lower the vacuum in the tube?

A. No.

XQ. 740. It did not?

A. No, it was not automatic.

XQ. 741. Oh, I see. You object to my use of the word "automatic"?

A. I mean that it was only because there were a great many other things in that lamp besides the tungsten filament that the vacuum became good. Many lamps having tungsten filaments showed vacuum that did not become good, but became worse. The mere presence of tungsten is not sufficient to get a good vacuum.

XQ. 742. Due to the improper exhaust of the lamp in its manufacture; is that right?

A. Or due to the presence of larger masses of metal. We never would have been able to build a lamp with large masses of metal, such as plate electrodes.

XQ. 743. Take your standard methods of exhausting incandescent lamps that were employed up to 1912, or were being employed at the time you began your first investigations, if the lamps and the interior of the lamps had been treated and processed and evacuated in accordance with the most approved methods employed up to that time, would that limit in use have decreased the pressure in the tube?

A. Yes, because of all these different factors taken together, not merely because of the tungsten.

XQ. 744. As a matter of fact, I think that you have stated somewhere that you had to have a high vacuum —no, you had to have a high vacuum in a tungsten lamp, because if you did not have it, you would break the filament by bombardment; is that correct?

A. You would get a shorter life if you had so much gas ionization that you had no space charge, then you would get too large currents flowing across the lamp, and the life of the lamp would be short, and might be destroyed immediately on a constant voltage circuit.

XQ. 745. And it was because of that that I think you testified that it was a very serious problem, and it was necessary to get the vacuum down so low that it would not happen; that is in effect correct, is it not?

A. I do not know what it is that you refer to as a "serious problem." I think I was talking there about the change in the conditions that were brought about by the introduction of tungsten as a filament material in place of carbon.

XQ. 746. I am not concerned with that problem, I am concerned with the proposition that that is the reason why you had to get as much air out of the lamp as possible?

A. I would not say as much as possible. We had to get the vacuum so good that this Edison effect would not unduly shorten the life of the lamp; that is as far as we needed to go.

XQ. 747. In other words, that bombardment due to ionization, bombardment of the filament due to ionization, would not unduly shorten the life of the lamp?

A. Yes, but that did not necessarily require the best possible vacuum.

XQ. 748. Now, you have referred to flashing and aging in connection with the incandescent lamp manufacture. I think we all understand what flashing means. You described that in your direct examination, did you not?

A. Raising the temperature of the filament, whether sudden or not, up to an abnormally high temperature for a short time.

XQ. 749. And what was aging?

A. Running the lamp for a certain length of time either at normal efficiency or normal voltage, or somewhat above normal voltage, in order to bring about whatever changes were going to take place during the early period of the life of the lamp.

XQ. 750. And you can describe them both as "heat treatment of the filament before they are commercially completed"; is that correct?

A. Partly that and partly to bring the vacuum in the lamp to a steady stage.

XQ. 751. And they were standard practice in the incandescent lamp art? At least, they were practiced and employed by the General Electric Company?

A. I think at that time, I think all lamps were given some aging treatment before they were shipped.

XQ. 752. Now, with reference to the work of Dr. Alexanderson, you stated in answer to Q. 108:

> "Mr. Alexanderson told me that he wanted to use an audion if an audion could be obtained that was not 'sluggish' in its action, for the purpose of using what he called tuning in geometrical progression."

And when asked to fix the time of this conversation, you answered:

This was in answer to Q. 109:

> "A. On February 4, 1913, I received a copy of a letter from Mr. Alexanderson."

Now, was the letter that you received from Mr. Alexanderson, which enabled you to fix the date, the letter dated February 5, 1913, from Mr. Alexanderson to Miss Orford of the Patent Department which

Mr. Davis has offered in evidence as Plaintiff's Exhibit No. 169 (indicating)?

A. I think I was mistaken as to the exact date. It was probably February 5—no. But that is not the letter. No, that is not the letter I had reference to, and perhaps the letter that I had reference to—in fact my recollection was that it was February 4, but it may possibly be February 5.

XQ. 753. Who was the letter from and who was the letter addressed to?

A. I think the letter was addressed to Mr. A. G. Davis, and a copy was sent to Mr. Hawkins and he turned that over to me at the same time that he gave me the audion.

XQ. 754. Have you got the copy of the letter that you referred to in your testimony with you?

A. No, I have not. I remember testifying about the letter in the case up in Trenton on the Alexanderson patent, which was where it came into my mind.

XQ. 755. You testified in the Alexanderson Interference case, the other parties to the Interference being Mr. Colpitts of the American Telephone & Telegraph Company, and Dr. DeForest?

A. I do not remember.

XQ. 756. I show you a record of that Interference. and I might state on the record that the testimony of Mr. Alexanderson that I read to him last night, was given September 17, 1919. Does this refresh your recollection as to whether or not you testified in that matter?

A. I suppose I did, but I do not really recollect it at present.

XQ. 757-58. Let me read this testimony that you gave, a portion of it. You may check it up.

"Q. 6. What was the disclosure which he made to you in February, 1913?

"A. At that time he told me that he proposed controlling the output of an Alexanderson high frequency generator by means of hot cathode, high vacuum electron discharge apparatus of the three-electrode type, applying potentials obtained from a telephone or microphone on the grid or three-electrode of the thermionic device. The plate or anode of the device was to be supplied with alternating current potential from the high frequency alternator and the alternator at the same time was to be used to excite an antenna for the purpose of sending radio telephonic signals. Alexanderson at that time had clear ideas as to how this could be accomplished as soon as proper thermionic devices were available. He knew that we were developing thermionic apparatus of the pure electron type which could operate at very high voltage and it was for that reason that he took up with me the question of building such high voltage, high powered thermionic devices. He wished particularly to know whether such devices would respond well to high frequency currents, or whether they might show a sluggishness in their action. I assured him that with the pure electron discharge such sluggishness would not occur."

Then you were asked:

"Q. 8. What steps, if any, did you take toward carrying into effect the ideas which Mr. Alexanderson disclosed to you?

"A. I undertook the development of high voltage three-electrode thermionic devices, having in mind that one of the main applications of these devices would be in connection with the radio telephony in the manner that Alexanderson had disclosed to me. This work progressed quite steadily from February, 1913, onwards. To illustrate the progress that we made in this direction I will refer to a few other entries in my notebooks. On pages 100 and 101 of my notebook 458, under the dates May 9th and 12th, 1913, I find entries which describe some tests made with some improved audions that Mr. White had made. These tests showed that these audions could be used for relaying or controlling high frequency currents with frequencies up to at least 75,000 cycles per second.

"On page 112, under the date May 12, 1913, I referred to some work which showed that the 'improved audions' which we had made, operated satisfactorily for high frequency currents. I stated: 'In this way we should be able to telephone by wireless: Using audion to magnify telephone vibrations and thus control the waves sent out by Alexandderson's alternator.' "

"On page 176 of notebook 458 under the date June 17, 1913, I refer to the fact that a new assistant of mine, Mr. William Rogers, is now working with Mr. White on audions. I said: 'At present the program is: Try out Alexanderson's plan of using telephone to control high frequency current and thus send telephone messages by wireless.'

"This work progressed steadily and Dr. Dushman and Dr. Hund, at my request, developed the high voltage, three-electrode tube and its application for radio telephony. On November 11, 1913, on pages 48 to 50 of my notebook 504, I made an entry describing the use of such a high-voltage three-electrode thermionic device 'with 10,000 volt high frequency current from Alexanderson's machine.' This entry describes the satisfactory nature of the results which proved that a high frequency power of about 300 watts could be controlled by the expenditure of a very small amount of energy applied to the grid. This work showed clearly that such a tube was suitable for use for radio telephony."

That is correct reading?

A. Yes.

XQ. 759. You so testified?

A. I believe so.

XQ. 760. And it was true to the best of your knowledge and belief at the time you gave it?

A. Yes.

XQ. 761. I want to ask you just one question in connection with Plaintiff's Exhibit No. 168, which was the curve of the output against the plate voltage of a three-electrode device, as an amplifier with gas, and a three-electrode device as an amplifier without gas, and I think that you testified as the result of the experiments on which this curve was based, that there is a point in a gassy tube where it operates in a very successful manner as an amplifier; is that correctly stated?

A. Yes.

XQ. 762. And I notice that your curve stopped on the gassy tube when you brought the voltage up to forty volts, the point being well below the steep part of the curve, which I understood you to state was the operating portion of the curve; is that correct?

A. Of course this is not a volt ampere characteristic at all.

XQ. 763. I understand that it is the amplifying quality of the tube, is it not?

A. Yes, but in your reference to the upward bending part of the curve, I think you were referring to volt ampere characteristics that I had previously spoken of and this is not at all comparable with that.

XQ. 764. I see, but as I understand this curve, the higher up on the millivolt ampere output ordinate that you go, the more sensitive the amplifier is; was that the purport of your testimony?

A. Why, we were plotting as ordinates the amplifying power, the amplifying power reached to a maximum at about twenty-seven volts.

XQ. 765. And the amplifying power of the tube at forty volts reached how much?

A. Well, it was very small; about 0.34.

XQ. 766. And what would have been the amplifying power of the tube, if you had raised it to fifty volts?

A. Probably very much less.

XQ. 767. In accordance with the slope of the last portion of the curve, it would be practically nothing, would it not?

A. Very likely. I do not know that. You can not safely extrapolate, because you go to higher voltages, the current becomes limited by saturation from the filament, and then the amplifying power becomes zero and remains zero, as higher voltages are reached.

XQ. 768. You referred to Dr. Lilienfeld's X-ray tube in your direct examination, and you expressed as your opinion, as I understood it, that Dr. Lilienfeld's X-ray tube operated because of gas ionization; is that correct?

A. That particular X-ray tube that we were talking about at that time—he has made many.

XQ. 769. I am confining myself to your testimony, the one that he showed in that article is the only one you considered in giving your testimony, was it not?

A. At that time, yes.

XQ. 770. Because if you are considering something else that was not in the case in giving your answer, I would like to know it now. In giving your answer to Mr. Davis' direct examination——

A. I thought maybe you were referring to other tubes besides that.

XQ. 770a. The testimony that you gave as to that was based entirely on that article?

A. Yes.

XQ. 771. All right. And your opinion that you expressed was based on assumptions that you made as to the dimensions of the tube and as to the voltages employed; is that correct?

A. I think they were hardly assumptions.

XQ. 772. Well, does the article state what the dimensions were?

A. It gives a figure, a diagram.

XQ. 773. No. Does the article state what the dimensions were?

A. No.

XQ. 774. Does the article state what voltages were employed?

A. It says the voltage was the city supply line.

XQ. 775. And you assume that to mean 250 volts or thereabouts?

A. Yes. It would not have made any difference whether it had been higher or lower in my conclusions.

XQ. 776. But it would have made a lot of difference if the dimensions were different, would it not?

A. No.

XQ. 777. Your conclusions—just a minute. You do not want me to understand from that that you reached your conclusions first, and then drew up the dimensions afterwards, to fit the conclusions, do you?

Mr. Davis: If your Honor please, I move to strike out the question.

Mr. Darby: I won't press it.

By Mr. Darby:

XQ. 778. Your conclusions would not have been altered in any respect if you had ignored entirely any dimensions or any value of voltages; is that correct; is that what you mean?

A. What I mean is this: I looked at the diagram that is shown there, and which Professor Chaffee has testified about, and Professor Chaffee has made an estimate of the dimensions of the tube I used——

XQ. 779. May I interrupt you there? As I recall Professor Chaffee's testimony, he made a guess as to the dimensions of the tube. I think those are his exact words.

A. I do not know the difference between a guess and an estimate.

XQ. 780. Well, he was requested to make a guess.

Mr. Davis: I beg your pardon. I do not think he was requested to guess.

Mr. Darby: I do not know whether your Honor recalls Professor Chaffee's language at that time.

The Court: I recall that with reasonable clearness, but is not your statement objectionable?

Mr. Darby: Yes, sir.

A. What I mean is this, or what I did was this, I looked at the diagram of the tube which tells us all we can ever find out about that tube as far as I know. I have no way of telling the dimensions of the tube in any other way than what is said in the article about it. A diagram is shown.

I first of all assumed a certain size for the bulb and from that drew the conclusion as to the distance between the anode and cathode in the auxiliary circuit. I also made the provisional assumption that the voltage was 200 volts and upon that I made a calculation from the space charge equations to find out how big the current flowing through the tube would be under those conditions and I obtained the result, I think, about five milliamperes as the reasonable current.

Then I saw from this result that it would not have made any difference in the final conclusion, that is, it would not have been any more possible to account for the observed current of 180 milliamperes if I had assumed any higher voltage within reason or if I had assumed different distances or different sizes of the electrodes within the reasonable range of possibilities.

In other words, I feel that I was justified in the conclusion, regardless of the specific assumptions that I may have made in my preliminary calculations. I know not only from those calculations but from my general experience with tubes of that sort that a pure electrode discharge current of 180 milliamperes is an impossibility with voltages of two or four hundred volts with a device of that character.

XQ. 781. And what size for the tube did you assume?

A. It does not make any difference.

XQ. 782. What size did you assume?

A. I think I assumed five or six inches as the diameter of the bulb but from the very nature of the problem if I had assumed one inch and taken the proportions as the same the results would be the same.

XQ. 783. The conclusions that you stated that you had arrived at with respect to the Lilienfeld article are not in any sense based upon the assumptions that you made as to the size, distance between electrodes and voltages employed, is that a correct statement?

A. I have stated exactly what I meant in my previous statement and all I can do is to repeat it.

XQ. 784. Then what is wrong with my statement?

A. There is this trouble, if I had made utterly unreasonable assumptions——

XQ. 785. I am not asking you whether your assumptions were reasonable or unreasonable. I am asking you if the conclusions that you advanced——

A. I want to say this, that the conclusions that I reached did not depend upon any assumptions that I could have made within reason, if I had made unreasonable assumptions I might have ——

XQ. 786. You are not answering my question.

(XQ. 783 repeated by the stenographer.)

A. In the first place——

THE COURT: That may require some explanation afterwards, but you can answer that first.

A. There is more than one conclusion that I reached and it is not clear which one you are referring to.

XQ. 787. The only one that I have mentioned thus far is that the Lilienfeld X-ray tube was a gas tube and operated because of the gas in the tube and was not a high vacuum tube?

A. Now, then, may I have the question again?

(XQ. 783 was repeated by the stenographer.)

A. I do not see how I can answer that yes or no.

XQ. 788. Let me reframe it then.

AFTER RECESS.

By MR. DARBY:

XQ. 789. With reference to the Lilienfeld X-ray tube I understand it was your opinion that its operation depends upon positive ions heating the hot cathode to free the electrons from the hot cathode; is that correct?

A. No, I did not say that. Positive ion bombardment of the cold cathode.

XQ. 790. Does positive ionization—its operation depended upon the presence of positive ions, that was your opinion, was it not?

A. Yes.

XQ. 791. And that the positive ions came from gas ionization in the tube?

A. Yes.

XQ. 792. Now, did you understand that Dr. Lilienfeld employed in his tube a Wehnelt cathode?

A. I think there are references to both Wehnelt cathodes and metal filament cathodes, but I think in the particular article that we were discussing at that time there was a definite statement that there was a metal filament.

XQ. 793. Metal filament?

A. I think there is a statement to that effect. Perhaps it may be in the Rosenthal article that goes with the Lilienfeld article.

XQ. 794. And you took that into consideration in reaching your conclusion, did you?

A. I did not say that it has anything to do with the reaching of the conclusion.

XQ. 795. Then you did not take it into consideration?

A. I think I took it into consideration, but I do not think it was pertinent.

XQ. 796. In other words, your conclusion would not have been different if you had known that he used a Wehnelt cathode?

A. No, it would not have been different.

XQ. 797. You know, do you not, that a Wehnelt cathode may furnish a considerable supply of positive ions in a high vacuum?

A. No, I do not know that. If it is not properly made it probably gives off gas and thereby leads to ionization.

XQ. 798. With reference to the Lamont tubes, you know what I refer to by that name, the tubes made on the Lamont pump in California?

A. Yes.

XQ. 799. I think you stated that they may possibly have been heated a little hotter than some of the DeForest bulbs, because of the Bunsen burner under it. If they were heated a little hotter by means of the Bunsen burner under it, would that have tended to free more water vapor from the interior of the walls?

A. It is a question not only of temperature but time and with proper provision for taking up gases. It is one factor that would tend that way but there are other factors that would have to be defined also.

XQ. 800. Taking into consideration the mercury that he had there.

A. The mercury pump would not remove water vapor.

XQ. 801. It would not remove water vapor?

A. No.

XQ. 802. So that in your opinion the mere heating of the bulb of Lamont with the Bunsen burner while it was on the pump would not have tended to relieve the interior walls of the glass of water vapor?

A. Of course, the more you heat it the more that factor would tend to remove water vapor from the bulb.

XQ. 803. And if the pump was operating it would remove water vapor from the bulb?

A. Not the pump but the pentoxide or the sulphuric oxid would have been more effective than the pump.

XQ. 804. At the present time in manufacturing vacuum tubes they use what is called the automatic exhaust machine, is that the correct name?

A. I think so.

XQ. 805. And do they not employ phosphorus pentoxide tubes in the exhaust lines of those machines?

A. Yes, sir, I suppose they do. I do not know about it. They may in some cases use liquid air.

XQ. 806. Do you know of any instance where they actually do use phosphorus pentoxide in the automatic exhaust machine?

A. I am not familiar with the practice in the automatic exhaust machine.

XQ. 807. Have you ever used phosphorus pentoxide in a portion of the machine which admits dry air into the tube?

A. What machine do you refer to?

XQ. 808. In any pumping system for evacuating three-electrode tubes?

A. I do not remember ever having done so.

XQ. 809. Are you familiar with the tubes manufactured on the Pacific Coast, the tube known as the Cunningham tube?

A. No.

XQ. 810. You do not know how it was made?

A. I have been told that the Cunningham tubes are made, a great many of them are made by the General Electric Company, but I do not know where.

XQ. 811. Have you ever heard of the expression rainbow flash?

A. I do not think I have.

XQ. 812. Do you know what kind of a flash material Cunningham employs in his tubes?

A. No.

XQ. 813. Have you yourself ever employed a flash containing sugar syrup, phosphorus and magnesium?

A. No.

XQ. 814. Never heard of its being used?

A. No.

XQ. 815. I think you testified this morning that you read over your specification before it was filed and believed at that time that the statements therein contained were true?

A. Is that a question?

XQ. 816. Did you?

A. Yes.

XQ. 817. Did you so testify?

A. Yes.

Mr. Darby: If your Honor please, I have completed the examination of this witness except with reference to one subject, namely, the disclosure by this witness to Dr. Coolidge, and in the interest of economy of time I do not want to examine Dr. Langmuir on that subject if Dr. Coolidge is going to be called, because it would merely require covering the same ground. If Dr. Coolidge is not going to be called, then I am not completed with this witness.

The Court: In the absence of assurance from the other side——

Mr. Davis: I am quite willing to agree that if Dr. Coolidge is not called, Dr. Langmuir may be recalled for cross-examination.

Mr. Darby: That will be entirely satisfactory.

Mr. Haight: With just one reservation on Dr. Langmuir's cross-examination. As I recall, the cross-examination of Dr. Arnold was not concluded, but the right to cross-examine him further was asked for and granted in the event that an examination of some of the notebooks of the Telephone Company would seem to make it advisable for the plaintiff to call him and we do not want the cross-examination of Dr. Langmiur concluded until that of Dr. Arnold is concluded.

The Court: Is that satisfactory, Mr. Davis?

Mr. Davis: Yes, if your Honor please. Of course the cross-examination of Dr. Langmuir—the only difficulty I have is that I assume the cross-examination of Dr. Langmuir should be with reference to his testimony.

The Court: Of course, it would have to be. I suppose Judge Haight has in mind the further cross-examination of Dr. Arnold may make advisable at least further cross-examination along certain lines of Dr. Langmuir's own testimony.

Mr. Davis: I think that is quite fair, your Honor, that it should be done.

Mr. Haight: That is all, then.

Re-Direct Examination.

By **Mr. Lunt:**

RDQ. 818. You have been asked as to certain flat-topped curves appearing in your *Physical Review* article for December, 1913, and I believe you were asked to look up certain further facts in connection therewith. If you have done so, will you please state what you have found?

A. I stated yesterday that I thought it was possible that the distance between the anode and cathode might have been changed between the time that the two curves were taken which were illustrated on page 463 of the *Physical Review* article. I find by examination of the notes of experiment 317 that that is actually what did take place.

The first curve which is referred to as curves 1 and 3 is obtained from the data which is on the record sheet 1348 of these notes and the curve marked 2 and 4 is from the data on record sheet 1364.

On record sheet S-1432-1 in the summary there given it is clear what the sequence is of the two curves and in between those two curves a magnet was applied to the bulb and the results show distinctly before and after that magnet was applied that the characteristics of the tubes changed in such a way as to indicate that the distance between the electrodes had been changed and I remember distinctly that that was one of the effects that occurred when the magnet was applied.

The way in which the curve changed at that time was in the direction that is indicated by the change in the space charge current indicated on page 463.

RDQ. 819. Referring to the DeForest audion with which you worked early in the spring or winter of 1913 and to the matter of sluggishness of such an audion which has been referred to, will you explain briefly what is this sluggishness and how it manifests itself?

A. I originally had been told by Mr. Alexanderson in January, 1913, that he had learned from Mr. Hammond that the audion was sluggish. I did not know the explanation of the phenomenon, but I believed that if such a phenomenon did exist it was probably in some way connected with the positive ionization in the audion which I felt sure existed from the fact that blue glow had frequently occurred.

When I visited John Hayes Hammond, Jr.'s laboratory in April I asked particularly what evidence they had that the audion was sluggish. And I found that the evidence was simply of this kind that if a strong signal was received, as for example, a static, or the result of static or any other sudden disturbance, the audion ceased functioning or its sensitiveness was decreased and it took some perceptible time before it came back to its original condition and that had convinced, or that was the reason given by Mr. Hammond and also by Professor Pierce, whom I met there, that was the reason that they gave for their conclusion that the audion was sluggish.

Later on, or shortly thereafter, I realized that that sluggishness that they had observed was not the sluggishness of the tube itself at all, but was the sluggishness of the condenser discharge itself, and that effect could be overcome by using a grid leak. In regard to whether or not the audion itself was sluggish, I did not know at that time, and I really never gave the matter any consideration. But I know now from a general knowledge of the theory of the tube, and also from the fact that gas-filled tubes such as the 200 tube, which contains a relatively large amount of argon is not inherently sluggish. It can be used for example as a radio frequency amplifier perfectly well. It makes a perfectly good amplifier for radio frequency currents even when there is positive ionization and thus the electrons respond to high frequency potentials.

RDQ. 820. Did you demonstrate to Mr. Alexanderson during the early part of the year 1913, one of your tubes, and if so, what tube, and what are the circumstances?

A. In notebook 458, on page 100, under date of May 9, 1913, I made an entry that I showed some of the audions that White had made up to Mr. Alexanderson. I remember that conversation that I had with him at that time very well, and I remember that very shortly thereafter, judging from my notebook, probably on May 12, 1913, I took these tubes over to Mr. Alexanderson's laboratory and worked with him in studying their response to high frequency currents and I know that the tubes that I used at that time were high vacuum tubes of the type illustrated by audion No. 2. I believe, as a matter of fact, that one of the tubes used was actually audion No. 2.

Mr. Lunt: That is all.

The Court: Any further cross-examination?

Mr. Richmond: Yes, sir.

RE-CROSS-EXAMINATION.

By Mr. Richmond:

RXQ. 821. In regard to that Figure 3 on page 463 of your *Physical Review* paper of December, 1913, it is a fact, is it not, that before this change in the filament spacing to which you refer, the high vacuum value of the current in amperes per square centimeter, was 0.0100, and——

A. I beg your pardon?

RXQ. 822. (Continuing.) 0.0100——

A. Yes.

RXQ. 823 (Continuing.) —and after the change in the filament spacing, the high vacuum value of the current was 0.0109; is that correct?

A. I may be looking at a different thing from what you are, Mr. Richmond, but I get the first figure but not the second one. I do not see where you get that figure. Perhaps you will read the question. (Previous questions repeated as recorded.) I do not see the point of the question. The voltages were different, and the pressures were different, but the mere change in voltage alone would have caused the change, and I do not see where the 0.0109 is on the diagram at all. Do you want me to go into detail to discuss these results? I can tell you everything that happened at least.

RXQ. 824. First, tell us how you get that value 0.0100, to which you agreed, I understand?

A. The curve which is marked 3, as the temperature is raised, approaches the limiting value which is 0.01 amperes per square centimeter; that is ten milliamperes per square centimeter, that was at 177 volts on the anode. Now, later on, with hydrogen in the tube and with 148 volts on the anode, a current of—about 15.5.

RXQ. 825. What page of the notes?

A. I am not looking at the notes. I am looking at the *Physical Review* article, the diagram in the *Physical Review* article——

RXQ. 826. All right. Thank you.

A. The corresponding part of the curve, flat part of the curve was 15.5 milliamperes per square centimeter. Now, as I said in between those two runs, the distances between the two filaments had been changed; in fact, the filaments had been brought closer together by the forces that had acted on them as the result of the magnetic field. Now, another fact that I want to call attention to is that the pressure during that run was not constant, but as noted on page 464 of the *Physical Review* paper, the pressure decreased from 7 microns down to 4. Now, looking up the data of record sheet 1364, I find that the current was actually 5.4 milliamperes and the pressure during that part of the run where the curve was flat, was 3.8 microns, that is, it had gone down from about 7, and I gave a round figure of 4. Actually it was 3.8 microns at that time.

Now, if you wish to make a comparison—I suppose that's what you wish to do in asking me about these curves, was to make a comparison between the currents on the flat-topped part of the curve—the changes in current that resulted from the gas pressure, disregarding facts such as the distance between the electrodes, I would suggest that that comparison can be more fairly made by comparing the curve 4, which is the one that occurs in Figure 3, page 463 of the paper, where the current was, as I have just said, 5.4 milliamperes at 148 volts, you can make the comparison better by comparing that curve with the curve obtained just after that, and which is referred to in the middle of page 464, where the value *b* is given as 55,600. Now, those data occur on the records of Experiment 317, on page 1366, and there again, there is a flat-topped part of the curve. You see the vacuum was good in that case. It was relatively good. It was one-quarter of a micron as compared with the 3.8 microns in the run above. The voltage was 167, and the current on the flat-topped part of the curve was 4.1 milliamperes, and the difference between the 5.4 and the 4.1, as the vacuum improved, was due to the effect of positive ions in modifying to some extent, the electron space charge; that is, with the 4.1 milliamperes, the current was limited by space charge practically independently of positive ionization, and then the pressure was 3.8 microns of hydrogen, there was enough positive ionization to have raised the current from 4.1 up to 5.4. That much of effect can be said to be due to the effect of positive ions.

I have gone over the data in Experiment 317 with a great deal of care, and I find that on the last few pages, there is a very complete summary of all the experiments on just this effect. With 3.8 microns of hydrogen the space charge was only partly neutralized. With eight microns of hydrogen, even with a very much lower voltage, a little over 100 volts, the space charge was completely destroyed and removed, so that the current rose right to the saturation value no matter how high the filament temperature was, but at 3.8 microns, you only had partial neutralization of space charge, that is, there is an intermediate region between the region where positive ionization has no effect, and the place where positive ionization completely neutralizes the space charge.

RXQ. 827. Now, please turn to page S-1374 of the notes, for Experiment 317, and I understand that this relates to a time after the change in the spacing of the electrodes, does it?

A. Yes.

RXQ. 828. And from the data on that page, can you calculate the current at 177 volts?

A. Well, there are two sets of data given on this page, one on the top and one on the bottom. Which one do you refer to?

RXQ. 829. The top of the page.

A. I do not see any figure of 177 volts but I see a figure of 181 volts. According to these notes I find that when the filament temperature was raised to 2390 and above (the temperature actually went up to 2620) at these very high filament temperatures the current was independent of the temperature, that is, it was a flat-topped curve and the value of that current was practically exactly four milliamperes and the voltage was 181 volts.

RXQ. 830. And how much is that per square centimeter?

A. 11.2 milliamperes per square centimeter.

Mr. Richmond: That is all.

(Witness excused.)

Mr. Davis: If your Honor please, I entered into an engagement the other day to ascertain the facts with reference to the sale of thoriated filament lamps as distinguished from Battersea lamps and I have a letter from Mr. H. B. Rogers, of the Harrison Works, or of the Incandescent Lamp Department of the General Electric Company, which I have shown to Mr. Darby and it is agreed, as I understand it, that this letter is to be treated as evidence in this case.

Mr. Darby: I did not exactly mean that. For my purposes I would like to have it appear on the record some date on which there will be no controversy at which time thoriated tungsten filament lamps were on the market. Mr. Davis is now in a position to authoritatively state, as I understand it, that they were on the market at least as early as the fall of 1912, and his statement to that effect, irrespective of any letters would be entirely sufficient for my purpose.

The Court: All you have inquired for is the date?

Mr. Darby: Is a date.

Mr. Davis: I am sorry, but I dislike to make that statement without making an additional statement, which while it is very obvious I think should be made and that is that while Mr. Rogers has given me the date as the fall of 1912 as beginning to market tungsten lamps he goes on and says that it was a long time before we stopped selling lamps made with the Battersea filaments. They were in stock and it takes some time to change over and I want it to appear that we did not dispose of our final stock of lamps made by the Battersea process until the end of 1913 or very early of 1914.

The Court: You are not concerned with whether they are on the market?

Mr. Darby: I am not concerned with the fact of whether they are on the market today.

The Court: Then I understand that you stipulate with Mr. Darby that as to the date on which the thoriated tungsten filament lamp was on the market was the fall of 1912 and you add of your own accord, Mr. Davis, the supplementary statement to which Mr. Darby does not object but asserts it is irrelevant.

Mr. Davis: Yes, sir, that is quite satisfactory. Also defendant's counsel have spoken to me and I think it appears on the record—Mr. Darby I have no doubt will agree with me, for the benefit of the Court of Appeals (it is not necessary here), that there was no thoria in the Battersea wire.

Mr. Darby: If that is the fact I will agree to that.

Mr. Davis: I will state it as a fact.

Mr. Darby: Then I agree to it.

Mr. Davis: On this question of the testimony given by Mr. Frank Waterman in a suit in New York we are willing to agree that the defendant may read into this case provided he does it today or tomorrow to give us reasonable opportunity to look it up, questions Nos. 18, 19, 20, 111, 120, 186, 195, 196 and 197 of the deposition of Mr. Frank Waterman given in behalf of plaintiff, the Marconi Wireless Telegraph Company of America in the suit brought in the Southern District of New York by that company against DeForest Radio Telephone & Telegraph Company, the testimony being given in the year 1916, and any or all parts of the answers to such questions with the same force and effect as if Mr. Waterman had testified in the present suit and had made these statements, understanding that that would mean that he had testified in this suit in the year 1916.

The Court: That is testimony would be given here as of that date?

Mr. Davis: Yes, sir, provided that the defendants stipulate that with like force and effect we may read into the case any other parts of the testimony of Mr. Waterman in that particular suit, and further——

Mr. Darby: That first is entirely satisfactory.

The Court: By first you mean up to this point?

Mr. Darby: Up to this point. That is, I think you correctly read the questions and answers that we went over. I mean you did not skip over any intentionally.

Mr. Davis: I hope that I did not. Provided that our expert Mr. Hogan may not only comment properly on Mr. Waterman's statements, as he may comment on any statement made by any witness of the defendant, but also may tell your Honor what it was that Mr. Waterman was talking about in each case. I do not mean by that anything more than to say that at this particular time Mr. Waterman was talking about a Fleming valve or at this particular time he was talking about something else, because I find myself in reading that testimony that they used names quite different from those we are using here and it is sometimes hard to find out what Mr. Waterman is talking about.

The Court: Then, of course, reserving to Mr. Darby the right to examine Mr. Hogan.

Mr. Davis: Oh, yes, and he may call a witness to show that Mr. Hogan is wrong.

Mr. Darby: That is perfectly agreeable. The only thing I want to make perfectly apparent is that I certainly will strenuously object to Mr. Hogan attempting to explain any of the testimony. If the testimony is ambiguous as to what he is referring to, whether it is a particular patent or structure, I am willing to have Mr. Hogan or counsel point out to the Court what he is talking about.

The Court: I rather suspected that there might be that reservation, but I wondered whether first if Mr. Davis had that mind, I think your statement was made out of an abundance of caution.

Mr. Davis: I wish to be very clear that Mr. Waterman used the word high vacuum and possibly highest possible vacuum and if Mr. Hogan can point out and show that he has used it in a certain way I think he is entitled to draw the inference and that he can leave to you the inference to be drawn.

The Court: I cannot make an abstract ruling now, an anticipatory ruling, but I think that the opportunity to do that should be equally open to both sides and that you mark the trail which the other side will be able to follow.

Mr. Davis: I certainly will not do anything that the other side will not be permitted to do.

The Court: So that it will be understood that as far as Mr. Hogan goes the other side will likewise have an opportunity to do the same.

Mr. Davis: The reason given, or one of the reasons given by Dr. Arnold's counsel for taking testimony on the motion to dissolve in the Patent Office was that the meaning of terms had changed.

The Court: I can understand that. And it may be that that testimony given in 1916 would not be intelligible to a layman in 1926.

Mr. Davis: Further, it is stipulated and agreed for the purposes of this case that David Sarnoff who was then the commercial manager of the Marconi Wireless Telegraph Company of America testified on December 12, 1919, in that same suit, which was just mentioned, but before the Master on the accounting, "How long has it been since they ceased the manufacture of the two-electrode device shown in the Fleming patent as distinguished from the Wegant type? A. I believe if my recollection is not faulty in this, that the America Marconi Company always acquired its two-electrode tubes from its affiliated company in Great Britain, and I think that the British Company still continues to manufacture two-electrode tubes," and that if called as a witness Mr. Sarnoff would testify to the same effect in this case.

Mr. Darby: That is correct. That is satisfactory.

The Court: That covers all that you want?

Mr. Darby: All that I want plus the additional statement to which I understand Mr. Davis has no objection, that Fleming——

Mr. Davis: The statement which my brother wants is that Professor Fleming had assigned his British patent to the British Marconi Company.

The Court: And that you stipulate?

Mr. Davis: Yes, and he also asked me to say to your Honor something about Mr. Frank Waterman but I think all the Judges in this part of the country know who Mr. Waterman is.

The Court: I think he testified to his qualifications in the other radio suit. I may read into this record the qualifications stated by him in this case.

Mr. Davis: Yes, I think what Mr. Darby wanted to say was that his qualifications were admitted in the suit to which we have referred and of course Mr. Waterman is a consulting-engineer who has testified in many patent cases.

My attention has been called during the last day or two to some statements contained in an application of Dr. Arnold which became a patent and it seems to me to be relevant and the sort of thing that one may put in evidence. If these were used to contradict the testimony of a party I would not be obliged to show them to Dr. Arnold, as I understand it, but Dr. Arnold is not personally technically a party to this case and I am wondering whether——

THE COURT: You may recall him back for the purpose of cross-examination and present that to him. You may do it now.

MR. DAVIS: I would like to do that if it is a proper thing to do.*

ERNST F. W. ALEXANDERSON.

ERNST F. W. ALEXANDERSON, was called as a witness in rebuttal on behalf of the plaintiff, and having been duly sworn, testified as follows:

DIRECT EXAMINATION.

By MR. DAVIS:

Q. 1. Your occupation, please, Doctor?

A. I am consulting engineer of the General Electric Company, chief consulting engineer of the Radio Corporation of America.

Q. 2. How long have you been employed by the General Electric Company?

A. I have been employed by the General Electric Company since 1902.

Q. 3. And what connection have you had with the Radio Corporation?

A. Since the formation of the Radio Corporation, I was chief engineer for four years.

Q. 4. And during that period, did you retain your connection with the General Electric Company?

---

*For further cross-examination of Dr. Arnold, see page 785.

A. Yes, I never left the employ of the General Electric Company.

Q. 5. You know Dr. Langmuir?

A. Yes, sir.

Q. 6. Did you ever get in touch with him so as to come in contact with any work which he was doing on vacuum tubes?

A. Yes.

Q. 7. Will you state the circumstances, and about when it happened?

A. I had been interested in radio development for many years. In 1904, Professor Fessenden requested the General Electric Company to develop a high frequency alternator, and I was assigned to the job of doing this work. One of these machines was built and used by Professor Fessenden in his first test of radio telephony. I thus kept in contact with the problems of radio telephony, and I realized that modulation of large powers, of large frequency, was one of the essential problems.

> Mr. Davis: Just a moment, Doctor. I want to be sure that the Court understands what is meant by modulation.
>
> The Court: I think practically some one explained that to me.

Q. 8. That is the impressing of the signal on the out-going radio wave, Doctor, is that a correct statement?

A. Yes, that is right. Professor Fessenden used a large water-cooled microphone in series in the antenna, and thereby he varied the antenna current in response to the human voice, but I could see the limitations of the use of the microphone when larger powers were desired, so I started to work in various ways of relaying high frequency power, so that it could control a large source of high frequency by a comparatively small energy, derived from the microphone.

Mr. Davis: Pardon me interrupting the witness a moment. I want to be sure that that is clear to your Honor. May I state it simply as I see it?

Q. 9. You have in a radio station normally an out-going high frequency wave, perhaps a million cycles. In order that the signal may go out, you must change that because as long as it is not changed, no signal goes out, and when they talk about modulation from the telephone standpoint,—they mean changing the amplitude or the energy of that high frequency out-going wave in accordance with the voice wave or the other sound wave which goes into the microphone, so that if you draw a curve which represents the sound current, that would be the envelope of the high frequency curve; is that correct, Doctor?

A. Yes, that is correct.

Q. 10. Will you please go on from there?

A. As a solution for radio telephony on a large scale, I therefore conceived it necessary to have a telephone relay, and I started to work to develop the several forms of telephone relays, one of these was a rotating machine, a high frequency generator, which had its field excited by the telephone current, and the output current was then tuned and represented a large amount of energy modulated in accordance with the telephone current. That device was tested with successful results, but I could see its limitations, and I took up work along different lines that led to the development of a device which I called the magnetic amplifier which is now used in all our high power stations in this country, and in many stations abroad.

Q. 11. That is a modulating device?

A. That is a modulating device.

Q. 12. And it is used in these stations in connection with what generator?

A. Of a high frequency alternator.

Q. 13. Which is usually called the "Alexanderson Alternator"?

A. Yes.

Q. 14. And the other scheme that you thought of, of modulation?

A. The other scheme was a three-electrode mercury arc tube, with which I attempted to control the flow of current in a mercury arc by the third electrode. I obtained a patent on one of these devices, but I observed certain practical difficulties in the development in any of the devices that I had used, and was looking for something that would be still more adequate and particularly more sensitive. About that time I came in contact with John Hays Hammond, Jr., and he bought two of our high frequency alternators. I had in mind the special problems of supplying the modulation, and we discussed the use of the magnetic amplifier as a solution for these problems. We also had in mind special methods of reception, and Hammond told me about the audion. In accordance with Hammond's description of the characteristics of the audion, I thought it might be promising as a relay of high frequency; but after discussing that suggestion with him, I received the impression that the audion was in many ways inadequate, and I thought that the defects of the audion might be overcome, and therefore I agreed with Hammond that if he would give me an audion, I would take it up with the laboratories of the General Electric Company and see whether a more practical device could not be produced.

Q. 15. And what happened next, Doctor?

A. I took the matter up with Mr. Hawkins.

Q. 16. Who was he?

A. He was the executive assistant of Dr. Whitney, with whom I often discussed the laboratory affairs, and with Dr. Coolidge and Dr. Langmuir.

Q. 17. And what resulted from that?

A. I thought Dr. Coolidge and Dr. Langmuir might be interested in these possibilities, and I particularly discussed with Dr. Langmuir the design of a special high frequency relay, and he explained to me that the new type of discharge, high vacuum discharge, which he had discovered, was instantaneous, and would undoubtedly give the result which I had in mind if the tube was developed with three electrodes along these lines. I therefore arranged to get the audion from Mr. Hammond, and give it to Dr. Langmuir.

Q. 18. Now, when was this talk with Dr. Langmuir, approximately?

A. In January, 1913.

Q. 19. Do you recognize this paper which I hand you, and if so, what is it? (Handing paper.)

A. Yes.

Q. 20. What is it?

A. It is a letter to the Patent Department, in which I record my conservation with Dr. Coolidge and Mr. Hawkins.

Q. 21. This is your letter, is it not?

A. This is my letter.

Q. 22. And it is dated February 5. Was it written on that date?

A. Yes.

Mr. Davis: I offer the letter in evidence and I understand that defendants having seen it, will accept the copy in place of the original. The date is February 5, 1913.

(Received in evidence and marked "Plaintiff's Exhibit No. 169." *See Volume IV, Plaintiff's Exhibits, page 57.*)

Q. 23. Now, what did Dr. Langmuir say to you he could accomplish by the changes which he proposed to make, or which resulted from the talk; what was the expected improvement in other words, as it was then discussed?

A. I had the impression that the audion was sluggish and therefore would not operate properly at high frequency, and he told me that the high vacuum discharge would not have that defect; also I had received the impression from Hammond that the audion would saturate at very low energy levels, and I was told that the high vacuum discharge could be used at high voltages and in high power.

Q. 24. Do you know as a matter of fact whether Mr. Hammond was right in his statement about the sluggishness?

A. I have no direct experience with the audion.

Q. 25. But at the time you believed it, and that is one of the things that led you to talk to Dr. Langmuir?

A. Yes.

Q. 26. Now, what were the two uses which you particularly had in mind for the audion, if it could be improved as suggested?

A. One use was regarding the system of reception, and the other was for modulation of high frequency for transmission of radio.

Q. 27. Let us talk first of the new system of reception; what is the name of that new system?

A. I called it tuning in geometrical progression.

Q. 28. And were you tuning the radio or the audio frequencies?

A. It was radio frequency. The object of the system was to attain selectivity of the higher order than had been realized previously, because I imagined the development of radio on a large scale, and I thought it essential to have ways of discriminating between a distant station and a nearby station.

Q. 29. And were tubes produced or not for this test, for a test of this geometric system?

A. Yes, I had worked out the theory for tuning in geometrical progression. I told Dr. Langmuir about it, and asked him to develop tubes by which a practical test could be made.

Q. 30. What was the result of that request?

A. He started work immediately, and quite soon he was in a position to make a test, which entirely confirmed my theory.

Q. 31. And did you actually operate this system of geometric tuning?

A. Yes, the system of geometric tuning was introduced——

Q. 32. I beg your pardon, Doctor. I want to make it quite clear whether or not at this time, when Dr. Langmuir produced these tubes, you actually used this system of geometric tuning?

A. Yes.

Mr. Darby: If your Honor please, I object; I do not see the materiality of this at all.

The Court: I will hear you, Mr. Davis.

Mr. Davis: Dr. Langmuir has testified that these tubes, one of the tubes which was introduced in this test, was audion No. 2, which is one of the audions in controversy here, and I am trying to show by this witness the proper operation of audion No. 2 in a geometric reception.

Mr. Darby: I will withdraw my objection to audion No. 2, if it was one of the ones that Dr. Alexanderson employed.

Mr. Davis: Dr. Alexanderson informed me last night that he has no recollection whatever of this arbitrary audion number, but Dr. Langmuir has testified, if I remember correctly, that audion No. 2 was so used, and Mr. White will testify. It is the question of the audion, if your Honor please.

The Court: Mr. Darby withdraws the objection.

Mr. Davis: And regardless of audion No. 2, it was these audions, whether it was No. 2 or 3, or 4.

The Court: That is where I——

Mr. Davis: May I ask a question, and see if I raise the question?

The Court: You withdraw the present question?

Mr. Davis: I withdraw the present question.

By **Mr. Davis**:

Q. 33. You have said that the test was made. Can you approximately fix the date of that test; I mean, about when it was?

A. Yes, the test was made in the spring of 1913.

Q. 34. Now, in that test, how many tubes were used?

A. I think two tubes were used.

Q. 35. And where did those tubes come from?

A. They were produced by Dr. Langmiur and his assistants, and the test was supervised by my assistant, in my laboratory.

Q. 36. And approximately what voltages were used on the B-batteries of these tubes?

A. I think they used a couple of hundred volts.

Q. 37. And how did the tubes operate?

A. The tubes operated as a repeating relay, transforming radio frequency energy from one circuit to the next, entirely as I expected.

Q. 38. And was the operation or not satisfactory?

A. It was entirely satisfactory.

Q. 39. Has this geometric tuning system gone into use on an extensive scale?

Mr. Darby: I object to that. That is not material to the issue.

(Discussion.)

Q. 40-42. You spoke of the desire to obtain a modulation of radio energy?

A. Yes.

Q. 43. What connection had that with these tubes that Dr. Langmuir showed you? What was the history of that situation?

A. I had been working with various ways and methods of modulating radio frequency energy and I saw in the three-electrode tube or discharge a possibility of realizing these intentions and so I discussed with Dr. Coolidge and Dr. Langmuir the design of the high power tube for that purpose and Dr. Langmuir took up the work immediately and set some of his assistants to work on producing such tubes.

Q. 44. I hand you here another paper. Do you recognize it?

A. Yes.

Q. 45. This is your letter?

A. It is my letter to the Patent Department.

Q. 46. Dated May 14, 1913?

A. Yes, sir. In that letter I gave the theory——

Mr. Darby: May I interpose an objection after the witness has answered the question?

The Court: Yes. You need not state what is in the letter, Dr. Alexanderson.

Mr. Davis: I will read one sentence of the letter.

Mr. Darby: And I will object.

The Court: Do you offer it in evidence?

Mr. Davis: Yes.

Mr. Darby: I object to its receipt as being wholly immaterial and irrelevant.

(Discussion.)

Q. 47. May I ask Dr. Alexanderson: Will you read the first page of the letter, the sentence beginning "Dr. Langmuir demonstrated"? Read it to yourself and then tell us if you remember that incident?

A. Yes, sir.

Q. 48. Do you remember the incident?

A. Yes.

Q. 49. Are you able to fix the date of the incident other than by the date of the letter?

A. Not exactly.

Mr. Davis: I have no desire to put the letter in if it is understood that that date is fixed as May 14, 1913. I am quite content to have the witness describe what happened.

Mr. Haight: I do not know what the question is.

Mr. Davis: May I read what the letter says?

Mr. Haight: No. We object to the letter.

(Discussion.)

Q. 50. Do you remember the demonstration referred to?

A. Yes, sir.

Q. 51. As a matter of your own recollection without any reference to this letter at all?

A. Yes.

Q. 52. Will you please state what the demonstration was?

Mr. Darby: I object to that.

The Court: That is the fundamental thing to which you object?

Mr. Darby: Yes, sir.

The Court: I will have to be informed about that.

Mr. Darby: My objection is on the ground that it is irrelevant and immaterial.

Mr. Davis: I do not know that my brother knows what it will be until the witness answers it. May I ask this question to clear the ground?

Q. 53. Did or did not this demonstration consist of a demonstration of a vacuum tube by Dr. Langmuir?

A. It consisted in the demonstration of a vacuum tube.

Q. 54. Now, will you please tell us what the demonstration was?

Mr. Darby: Will you carry it just one step further and would you ask the witness whether it was a demonstration by Dr. Langmuir using a vacuum tube for relaying high frequency current, the demonstration taking place presumably on or about May 14, 1913?

Q. 55. I ask that question.

A. Yes, I recollect the circumstances.

Q. 56. And it was a demonstration of a vacuum tube for relaying high frequency current?

A. Yes, sir.

Mr. Darby: I have no objection up to that point, but going beyond that point I object for the same reason that I advanced before. On the question of utility we have never denied utility of a three-electrode vacuum tube either with or without high vacuum.

The Court: There is no question pending now.

Mr. Darby: No, sir.

Q. 57. What was that demonstration?

Mr. Darby: I object to that as irrelevant and immaterial, what the demonstration was.

(Discussion.)

Mr. Darby: I will withdraw the objection.

Q. 58. What was this demonstration?

A. May I have the letter again to refresh my memory?

Mr. Darby: Does your offer of proof extend to this: I understood you to say that you would prove by Mr. White that the tube used in this demonstration was one of the tubes mentioned by Dr. Langmuir.

Mr. Davis: No.

Mr. Darby: Then I renew my objection.

(Discussion.)

The Court: My thought is that it does come down to that because it may show that if the tubes here used were Langmuir tubes that they were so far removed from the DeForest tubes in their functions and the work that they would do as to show invention existed somewhere between DeForest and Langmuir, and that would be another question as to who was entitled to the patent.

Mr. Davis, are you going to identify these tubes used in this demonstration as tubes made by Dr. Langmuir in conformity with the process of this patent?

Mr. Davis: Yes, sir.

The Court: Then you withdraw your objection.

Mr. Darby: On that assurance, yes.

Mr. Davis: We will have to recall Dr. Langmuir to do it unless Mr. White happens to remember it.

Mr. Haight: There is one point that I do not want to let go unchallenged and that is Mr. Davis' remark that they built the transmitting tubes that made possible transmission, because my friends of the Telephone Company utter wild protest to the effect that they did it.

By Mr. Davis:

Q. 59. What was this demonstration?

A. Dr. Langmuir demonstrated to Mr. Hawkins and to me one of the tubes which he made in accordance with my request and the tube proved to be capable of operating at high voltages and constituted a very promising solution of the problem which I had asked

Dr. Langmuir to solve, that is, to provide a modulator for high powers.

Q. 60. You fix the date as May 14th——

A. May 14th, 1913.

Q. 61. By the date of this letter?

A. Yes, sir.

Q. 62. Was any further work done in connection with Dr. Langmuir and his assistants in this same connection with the modulator?

A. Yes. I discussed the probable characteristics of some more powerful tubes and was informed that such tubes would operate to advantage at voltages as high as 40,000 volts.

Mr. Haight: I move to strike it out.

Mr. Davis: I want that simply as Dr. Langmuir's confidence of what he could do.

The Court: He did not say that that was a disclosure by Dr. Langmuir to him.

Mr. Davis: Then I will consent to have it stricken out.

The Court: Motion is granted.

Q. 63. Did Dr. Langmuir or did he not make any statement to you as to what voltage should be employed when the device went into use on a commercial scale?

A. He indicated voltages as high as 40,000 volts might be used.

Q. 64. And were any further later tests made on this modulator?

A. The tube was built which was tested in my laboratory at 40,000 volts with our high frequency alternator.

Q. 65. And that was when?

A. In the fall of 1913.

Q. 66. And about how much energy was utilized in that tube?

A. Two kilowatts alternator.

Q. 67. Does that mean that the tube was handling that power?

A. The tube controlled the power in the sense that it switched two kilowatts of power into the antenna and reduced it to nothing, but the tube itself did not consume all that energy.

Q. 68. The tube was handling all that energy?

A. Yes.

Q. 69. And how well did the tube operate in that test?

A. The tube operated entirely successfully.

Q. 70. And this method of modulation which you invented at that time did you patent?

A. Yes.

Q. 71. Was there some delay in getting the patent?

A. Yes, interference was declared with Colpitts and DeForest.

Q. 72. Colpitts of the Telephone Company?

A. Yes.

Q. 73. And DeForest of the DeForest Company?

A. Yes.

Q. 74. Who won the interference?

A. The patent was granted to me.

MR. HAIGHT: I object. It is immaterial. Mr. Ballard says they got half of it.

THE COURT: It is already in the record.

MR. DAVIS: You may cross-examine.

CROSS-EXAMINATION.

By MR. DARBY:

XQ. 75. In this modulator, how many volts did you employ on your plate in 1913?

A. We employed voltages as high as 40,000.

XQ. 76. 40,000 volts on the plate electrode?

A. Yes, sir.

XQ. 77. Did you use that in the form of a B-battery, that is, that took the place of the B-battery?

A. We applied the high frequency currents from the alternator.

XQ. 78. 40,000 volts?

A. Yes.

XQ. 79. As I understand your testimony you first saw an audion at Mr. Hammond's; is that correct?

A. I do not think I saw the audion at Mr. Hammond's, but I discussed the use of the audion with Mr. Hammond.

XQ. 80. You had seen an audion prior to that time?

A. No.

XQ. 81. You had not?

A. No.

XQ. 82. You do not recall whether you actually saw an audion the first time the subject was discussed with Mr. Hammond?

A. I do not recollect seeing an audion.

XQ. 83. When do you recollect that you saw an audion?

A. When the audion was sent—when I received the audion from Mr. Hammond.

XQ. 84. At Schenectady?

A. Yes.

XQ. 85. And as I understand you, you asked Mr. Hammond to send you that audion?

A. Yes.

XQ. 86. And the reason why you wanted to get it was so you could try out this geometrical tuning; is that correct?

A. That was one of the reasons, but I had in mind other uses of a high frequency relay.

XQ. 87. But you disclosed your reasons to Dr. Langmuir, did you not?

A. Yes.

XQ. 88. And the reason that you disclosed to Dr. Langmuir was a high frequency relay?

A. Yes.

XQ. 89. And that high frequency relay did not employ geometrical tuning, did it?

A. The geometrical tuning was one of the objectives for which I needed the high frequency relay.

XQ. 90. But you disclosed to Dr. Langmuir only the high frequency relay. You did not disclose to him the geometrical tuning?

A. Yes, I discussed the geometrical tuning with him.

XQ. 91. Then, as I understand you, the reason why you obtained the audion from Mr. Hammond was that you wanted to obtain not only a high frequency relay but a geometrical tuning arrangement and that you told that to Dr. Langmuir before you got the audion; is that correct?

A. I told him in advance before I got the audion that the geometrical tuning and high frequency relays and other purposes were some of the objects I had in mind.

XQ. 92. And those objects are what you told Dr. Langmuir before you got the audion?

A. Yes, sir.

XQ. 93. You have also mentioned sluggishness. You have used the word that the audion was sluggish. What did you mean by that?

A. I had been working with mercury arc devices before and I had found some difficulties in its use which I explained in my mind as sluggishness. Then when Hammond told me about the inadequacy of the audion I also interpreted that as sluggishness.

XQ. 94. Then you had explained to your own mind that the audion was sluggish before Mr. Hammond told it to you; is that right?

A. I did not know about the audion until Mr. Hammond told me about it.

XQ. 95. Did Mr. Hammond tell you that the audion was sluggish?

A. Yes, I received that impression from him in discussing the use of the audion for a certain purpose that I had in mind.

XQ. 96. Did you explain to Dr. Langmuir this sluggishness of the audion as it had been explained to you by Mr. Hammond?

A. Yes, I told him that I understood that that was one of the defects of the audion.

XQ. 97. And did Dr. Langmuir tell you that that was due to gas in the audion, when you made that explanation to him?

A. I think he indicated that as a probable explanation.

XQ. 98. Are you quite sure that he indicated that to you?

A. That is my recollection.

XQ. 99. And he indicated that to you before you made any such suggestion to him, did he not?

A. I do not remember how the matter was mentioned in our conversation, but I recollect that we both came to the conclusion that if the audion was defective it was very likely owing to the presence of gas.

XQ. 100. See if I can refresh your recollection in the testimony which you gave in the Interference proceeding. Do you recall testifying in the Interference proceeding in your own behalf, do you not?

A. Yes.

XQ. 101. Do you recall testifying as follows in answer to Q. 5:

> "During the fall of 1912 and the early part of 1913, I made several trips to the experimental

radio laboratory of John Hays Hammond, Jr., of Gloucester, Massachusetts, where two of my 100,000 cycle alternators were installed for experimental purposes."

You may check up with me to make sure I am right, Doctor, and that I am reading it correctly:

"During the progress of the tests I conducted with Mr. Hammond we had various discussions of radio problems in general and particularly of the problem of telephonic modulation of high frequency energy. During these discussions Mr. Hammond told me about the characteristics of the DeForest audion, and I gained from him the impression that while the audion had proven to be an efficient amplifier of telephone currents, it could not be used as a relay for radio frequency currents, because of an inherent sluggishness in its action. In connection with my experimental work with mercury vapor relays of the type described in my patent No. 1,042,069, I had noticed a certain sluggishness in the action of these tubes, and in my own mind I explained this sluggishness as due to the inertia of ionized vapor. I was, on the other hand, in a general way familiar with the results of the work of Dr. Langmuir and Dr. Coolidge in connection with X-ray tubes, and I was under the impression that the sluggishness which I had observed would not exist in vacuum tubes of the type that Dr. Langmuir and Dr. Coolidge were dealing with. I therefore conceived the idea that the three-electrode valve of the DeForest type might be improved by the methods of evacuation used by Dr. Langmuir and Dr. Coolidge, and that the tubes so improved might be substituted in the system for radio telephonic transmission described in my patent 1,042,069."

And then you were asked:

> "Q. 6. When did you first disclose this idea to others?"

To which you answered:

> "A. After one of the discussions with Mr. Hammond, which I referred to, I communicated my ideas to Dr. Coolidge and Mr. Hawkins. Dr. Coolidge confirmed my opinion as to the probable results of the use of a higher grade of vacuum in a tube of the DeForest type, and was in favor of research work being started along this line. For this purpose I obtained from Mr. Hammond a sample of a DeForest audion, which I gave to Dr. Langmuir, who had taken up this investigation."

That testimony was true at the time you gave it, was it not, Dr. Alexanderson, and is now?

A. Yes.

XQ. 102. And the patent that you referred to in the testimony, No. 1,042,069, is the one, a copy of which I now show you?

A. Yes, that is right.

Mr. Darby: I ask to have it marked for identification.

(Received and marked "Defendant's Exhibit K for Identification.")

Mr. Darby: I think that is all.

The Court: Any re-direct, Mr. Davis?

Mr. Davis: No re-direct, if your Honor please. That is all, Doctor.

(Witness excused.)

(Whereupon, at 6 P. M. adjournment was taken until Thursday, November 4, 1926, at 10 o'clock A. M.)

WILLIAM C. WHITE.

William C. White, was called in rebuttal as a witness on behalf of the plaintiffs, and after having been sworn, testified as follows:

Direct Examination.

By Mr. Davis:

Q. 1. What is your occupation, Mr. White?

A. Research engineer for the General Electric Company, employed in the research laboratory at Schenectady.

Q. 2. How long have you been employed by the General Electric Company?

A. Continuously since July, 1912.

Q. 3. And was it in the research laboratory all that time?

A. Yes.

Q. 4. Do you know Dr. Langmuir?

A. Yes.

Q. 5. And you have been working for him for how long?

A. I worked immediately under his supervision for a period of several years, and have been closely associated with his work until the present time.

Q. 6. And what is the time when this period began at which you worked immediately under his direction?

A. The early part of 1913.

Q. 7. And what had you been doing before that?

A. I had been employed on experimental work in connection with mercury arc devices.

Q. 8. I hand you a notebook which has been marked "Plaintiff's Exhibit F for Identification," and ask you if you recognize it?

A. I do.

Q. 9. What is it?

A. It is my notebook No. 452.

Q. 10. Covering approximately what period?

A. Covering approximately the period between January, 1913, and April, 1914.

Q. 11. And were the statements herein recorded correct at the time of the record, to the best of your knowledge and belief?

A. Yes.

Mr. Davis: I offer the notebook in evidence.

Mr. Haight: No objection.

(The notebook was received in evidence and marked "Plaintiff's Exhibit No. 171." *See Volume IV, Plaintiff's Exhibits, page 91.*)

Q. 12. I find in this notebook an entry on page 20. It is very short. Perhaps you had better read it, the last four lines.

A. On page 20, under date of Monday, February 10th, 1913, I wrote:

> "Spent afternoon in conversation with Dr. Langmuir in regard to some experiments I am to try with the DeForest audion."

Q. 13. Now, tell us about that conversation.

A. As stated in the previous answer, I had been engaged upon work in connection with mercury arc devices. Very shortly before making that entry, Dr. Whitney, the director of the General Electric Research Laboratory at Schenectady, came into the room where I was working and suggested that as soon as I could conveniently terminate the work I was then engaged upon, that I should spend all my time assisting Dr. Langmuir in connection with some thermionic work he was doing. Accordingly, the conversation recorded with Dr. Langmuir followed.

Q. 14. Did Dr. Langmuir or not show you any experiments or tests on this occasion?

A. At the same time that this conversation took place, or very shortly afterwards, Dr. Langmuir showed me some tests on a lamp with two filaments.

Q. 15. What was the general nature of the test?

A. The general nature of these tests was to illustrate how the current between a cold and hot electrode could be limited either by electron emission or space charge.

Q. 16. How did he illustrate this?

A. He illustrated this by putting a relatively high positive voltage on the cold electrode, and then slowly raising the filament temperature, showing that the current went up with this temperature. He also ran the filament at a normal temperature and increased the voltage on the cold electrode from zero to some relatively higher positive value, showing how also in this case the electron current increased with the voltage.

Q. 17. Were these increases indefinite?

A. No. He then illustrated that if the filament was run at a low temperature, an increasing plate voltage would only cause an increase of current through the tube up to a certain voltage value, and beyond that value, a relatively large increase of voltage did not cause appreciable increase in electron current.

Q. 18. What do you call that now?

A. I beg your pardon?

Q. 19. What do you call that now, that phenomena?

A. That is the phenomena we term "limitation of electron current by emission."

Q. 20. Is it also sometimes spoken of as "a saturation"?

A. Yes.

Q. 21. Now, Mr. White, in connection with the tests in which he varied the temperature, keeping the voltage constant, did that current go up indefinitely, or not?

A. No. He then used a normal positive voltage on the cold filament and raised slowly the filament temperature. Again, in this case, the electron current rose rapidly at first, and then above a certain point no appreciable increase of electron current was noted as the filament was raised to a still higher temperature.

Q. 22. You speak of the voltage being put on the cold filament; actually where were the terminals of the source connected?

A. As I remember it, this tube had two parallel hairpin filaments, so that it had four wires coming out of the stem. One of the pairs of wires went to the cold filament which was used as the positive terminal.

Q. 23. And what was the negative terminal?

A. The negative terminal was the hot filament.

Q. 24. Now Dr. Langmuir having shown you those things, did he ask you to do anything?

A. He told me that he wished to build tubes in our own laboratory, and that he would obtain for me a DeForest audion to make the tests with, as he believed such a device employed electron currents.

Q. 25. Did he say anything about a vacuum system?

A. He told me that for the type of tubes he wished to make, I would have to install a much better type of vacuum system than I was employing in my mercury arc experimental work.

Q. 26. What did you do in that direction?

A. Shortly afterward I was able to obtain a Gaede Mercury Pump.

Q. 27. I do not now want the details, but simply whether you did or did not get a better vacuum system?

A. I did.

Q. 28. And still referring to this first interview, did or did not Dr. Langmuir give you specific instructions in reference to building any particular device?

A. Dr. Langmuir sketched out a tube which he wished constructed, and he wished me to exhaust and test.

Q. 29. Now, I refer to the entry in your notebook on page 23, February 13, 1913, to February 25, 1913:

"Away from lab. on account illness."

Do you remember that incident?

A. I do.

Q. 30. What was the situation when you got back with respect to this tube?

A. As I remember, progress had been made by the glass-blower in the manufacture of this tube, so that I was able later to start exhaust work upon it.

Q. 31. What was Dr. Langmuir's habit in a case of this sort with reference to dealing with the glass-blower?

A. His habit was to make a sketch of what he desired, and either to take it in himself or give it to one of his assistants to take in the glass-room, and very often in devices in which he was particularly interested, he would frequently go in to learn what progress was being made.

Q. 32. Now, on Thursday, March 13th, that is on page 32, under the heading, "Thursday, March 13 to Saturday, March 15," I find an entry. Will you tell us what happened on that day, according to that entry which you need not read unless you want to?

A. The entry covering March 13 to March 15th, states that "Completed vacuum system and exhausted an all-tungsten audion."

Q. 33. What audion was that?

A. No. 2 audion that we have spoken of.

Q. 34. First, I will ask you if you recognize this exhibit, this tube, which is marked Plaintifff's Exhibit No. 105?

A. I do recognize it.

Q. 35. What is it?

A. It is this audion, tungsten audion referred to. It is given No. 2.

Q. 36. And that is the audion referred to in your notebook as audion No. 2, is it?

A. Yes.

Q. 37. Was Dr. Langmuir present at the exhaust?

A. Not throughout, but at intervals.

Q. 38. Now, I hand you a collection of papers which are marked for identification, "Plaintiff's Exhibit G," and ask you if you recognize them (handing papers).

A. Yes, those are some of my record sheets made at that time.

Q. 39. Is there any part of them which is not in your handwriting?

A. Yes.

Q. 40. Is there any part which is not contemporaneous?

A. That same part that I am referring to as not being in my handwriting is not contemporaneous.

Q. 41. And that is on sheet numbers——

A. Eighty.

Q. 42. And in what column?

A. The last column to the right.

Q. 43. Now, how did this column of figures happen to get on this sheet, if you know?

A. I do not know under what circumstances they were put on that sheet, but they are not in my handwriting, and the initials are appended, indicating that they were placed there by another man in the laboratory.

Q. 44. Yes, you recognize these initials "C. G. F."?

A. Yes.

Q. 45. Then it is clear that this column was a later entry, something later than the original record; is that right?

A. Yes.

Q. 46. So far as you know, is there anything else in this collection of papers which is not contemporaneous and original?

A. No.

Mr. Davis: I note in that connection, if your Honor please, that these sheets of that early spring and winter, bear little different dates.

Q. 47. Now, I will first call your attention to this card which is on top. Is it a library or catalog card, or something of that sort?

A. Yes.

Q. 48. What is the date of that? The date of the card, I mean.

A. The date?

Q. 49. Yes.

A. April 30, 1913, is given on the card.

Q. 50. And what are the letters before the date?

A. "O. K."

Q. 51. Now, what does that mean?

A. This card was one of a number of cards that I used to keep track of the different tubes that came to me from the glassblower for exhaust and test. I did not start this system until a few weeks after audion No. 2 was built, and then made up cards for the first few tubes.

Q. 52. What does the "O. K." mean?

A. The "O. K." simply means that on April 30th, this tube was in satisfactory operating condition, and fit to use for miscellaneous tests.

Q. 53. I call your attention then to the sheet R. S. W.-77, headed: "Tungsten wire audion." What is that sheet?

A. That sheet R. S. W.-77 is a very brief record of the exhaust proceeding on audion No. 2.

Q. 54. The first column is headed: "Date." The second column is headed: "Time." What does that mean, "Time," on it?

A. Time of day.

Q. 55. The next is headed what?

A. "Microns pressure."

Q. 56. That little sign means microns, does it?

A. Yes.

Q. 57. And the next heading is what?

A. "Temperature."

Q. 58. Now, the pressure is what pressure? Pressure where?

A. The pressure is read on the McLeod gauge which was attached to the system near the tube.

Q. 59. What do you have, if anything, between the McLeod gauge and the tube?

A. A liquid air trap.

Q. 60. And this column marked "temp," what temperature does that refer to?

A. The temperature of the oven used for baking out the glass.

Mr. Davis: I do not know if your Honor cares to look at this; it is just a schedule of the exhaust, showing how long it was pumped, and so forth, and when the current was turned on (handing paper).

Q. 61. What does it mean, "Flashed filament well"?

A. That means the filament was operated at as high a temperature as I deemed it safe to operate without burning it out.

Q. 62. Now this audion had how many filaments?

A. This audion had a V-shaped filament, which was to be the cathode of the completed tube. The anode or plate was also in the form of a filament, strung back and forth between metal hooks, so that it could be heated by a current to free it from gas.

Q. 63. Now, the exact language of this entry is: "Flashed plate filament well and filament one." What does that mean, if I have read it correctly?

A. It is difficult for me to know now just what that was intended to mean, but I think it was to represent one of the filaments.

Q. 64. It says "and filament one, plate filament and filament one"?

A. That probably referred to the cathode.

Q. 65. And "sealed off at .05 mn"; is that it?

A. Yes.

Q. 66. That means microns?

A. Yes.

Q. 67. Now, the next sheet R. S. W.-78, will you please tell us what these headings refer to at the top of the columns, just read them across and say what they are briefly?

A. This sheet covers early tests on this audion No. 2. Starting from the left, the first column is the date. The next column is headed "Lamp amperes," which means current through the filament. The third column is headed, "Degree C, Abs.," which stands for absolute temperature. The next column is, "Plate Volts." The next two columns have a common heading, "Edison I," signifying electron current or Edison current, as we called it at that time. The first of these two columns with this common heading, is headed: "Meter," which signifies the meter reading, and the second column under this heading, "Milli Amps.," which signifies the reading of the meter transferred into terms of milliamperes.

Continuing to the right, another test is recorded, the first column of which is again "Amps. Lamp." Next, "Degrees C. absolute." The next "Plate Volts," and again two columns with a common heading, "Edison I." The first headed "Meter," and the second "Milli Amps." The final column had no heading, but was used to denote the calibration constant of the meter used.

Q. 68. What pump did you use in pumping this audion No. 2?

A. The rotating mercury Gaede Pump.

Q. 69. Was there anything between the Gaede Mercury Pump and the tube?

A. Yes, the liquid air trap.

Q. 70. I notice on this sheet R. S. W.-78, on the right-hand column, some figures, "K-107, K-1," and so forth. Will you please explain what that means?

A. Those figures represent the calibration constant of the current measuring instrument used.

Q. 71. Why do they vary?

A. This is due to the fact that on this test, two instruments were used. One was direct reading, whereas the other required a correction constant.

Q. 72. That is, by "K-1," you mean it is direct reading?

A. Yes, sir.

Q. 73. Why were two instruments used, Mr. White?

A. Because the current range in the test was greater than could be accommodated on any one instrument I had available at that time.

Q. 74. That is, you would go up to a certain current on one instrument, and then what?

A. Change the instrument to one having the higher scale readings.

Q. 75. These readings were made and recorded by you on the date which that sheet bears?

A. Yes.

Q. 76. I hand you sheet R. S. W.-79, and that is dated 3/17/13, which I take it is March 17, 1913. Do the headings of the columns correspond in meaning to the similar entries on the last sheet that I showed you, sheet No. 78?

A. In general; there are additional columns on our R. S. W.-79.

Q. 77. Just tell us what these headings mean on those additional columns?

A. There is one column headed "Grid Volts"; another pair of columns headed "Grid I."

Q. 78. Which is what?

A. Meaning "grid current." The first of these two columns with this common heading have the word "Meter" at the top. The other column has the word "Milli Amp."

Q. 79. And these sheets record the tests that were made by you on that day?

A. They do.

Q. 80. What was the energy approximately in the audion in that last test?

A. In the last test?

Q. 81. On the test in that last sheet I should say, that is, sheet 79.

A. I notice in one case with a plate voltage of 115 a current of 11 milliamperes is recorded.

Mr. Davis: This sheet R. S. W. 80 we are putting in for completeness. I have already called attention to the fact that somebody has made some marks on it which are not contemporaneous and it also has the fault that Mr. White has forgotten to date it.

The Court: That is the 1-2/3 column.

Mr. Davis: Yes, it was very recent.

The Court: You are excluding that column from the offer?

Mr. Davis: Oh, yes. It is no part of the record and it is apparent that somebody up there who did not know any better simply made those marks on that sheet.

Q. 82. Do you know about when this particular sheet was made excluding this column?

A. Yes, it is a sheet following after R.S.W. 79.

Q. 83. And preceding 81?

A. Yes.

Q. 84. And 81 is dated when?

A. March 20, 1913.

Q. 85. So what do you know about the date of 80?

A. It was between March 17 and March 20, 1913.

MR. DAVIS: And the four columns in which we are interested here need not, I think, be explained. They have the same heading that the others had.

Q. 86. I hand you R.S.W. 81. Is that another of your original sheets?

A. It is.

Q. 87. And it is still recording tests on audion No. 2?

A. Yes.

Q. 88. And there are no terms there that you have not already explained, are there?

A. I notice one column is headed total current.

Q. 89. What does that mean?

A. There are no entries under the column so that I cannot be sure.

Q. 90. R.S.W. 98 is dated April 22, 1913. What is that?

A. This is another record sheet. Some of the entries refer to tests of audion 9-B and other readings of tests of audion No. 2.

Q. 91. I would like to go back for a moment to R.S.W. 81 and ask you what the nature of that test was, what you were trying to do when you made that test?

A. I was using a constant filament current and a relatively constant plate voltage and taking the readings of electron current and grid current with variations of grid voltage.

Q. 92. What was your object?

A. Probably to obtain the characteristic curve of variation of plate current with grid voltage.

Q. 93. There is an entry there "N.G. 115V not giving sat."

A. It is apparent that Dr. Langmuir had requested some particular curve showing saturation and that after carrying on a few readings this particular characteristic was not shown due to an improper choice of voltages and therefore the entry "N.G. 115-V not giving sat," meaning that this 115 volts was not giving saturation expected.

Q. 94. Why did it not give it?

A. Probably because the filament temperature was too high.

Q. 95. I notice on page 98 that the first quarter or perhaps sixth of the sheet has to do with another audion; is that correct?

A. Yes.

Q. 96. Otherwise the entries on that sheet refer to what?

A. Audion No. 2.

Mr. Davis: I offer the various sheets, which have previously been marked for identification G, in evidence.

(Received in evidence and marked "Plaintiff's Exhibit No. 172." *See Volume IV, Plaintiff's Exhibits, page 108.*)

By Mr. Davis:

Q. 97. I notice on page 34 of your notebook a statement that it was necessary to run the filaments for quite a time to get results consistent with previous day's results. First results 10 or 20 per cent. too high. What is that phenomenon?

A. It simply meant that plate currents were not the same immediately upon lighting the filament as they were a short time later. This effect very often occurred in some of our earlier tubes due to temperature effects on the mechanical construction causing expansion or contraction.

Q. 98. Will you illustrate that just what it might mean?

A. I think in those particular tubes it was due to the warping of the grid wires as the temperature of the parts was increased by the heat from the filament.

Q. 99. The grid was wound around the filament, was it?

A. Yes.

Q. 100. Has that happened since?

A. On well designed tubes it is not a common occurrence.

Q. 101. The effect would be to change the distance——

A. The probable effect was to change the relative distance of the grid either from the filament or the plate.

Q. 102. And thus change the amplification factor?

A. Yes, and also the plate current.

Q. 103. On pages 43 and 44 under date of April 7, 1913, there is an entry and I will first ask you, Mr. White, what these red ink marks which are I find on that page and in several places in the book?

A. They were placed there during an Interference proceeding in which this notebook was used some years ago.

Q. 104. That is, you were asked by counsel——

A. I was asked by counsel to mark certain places in the book for identification.

Q. 105. And any red ink in that book, is that sort of an entry?

A. Yes.

Q. 106. Now, tell us what the nature of these tests were referred to on those pages?

A. On page 43 there is recorded some notes of a scheme suggested by Dr. Langmuir to step up direct current from one voltage to a higher voltage. On page 44 an arrangement for a similar purpose is described.

Q. 107. That is, by means of what?

A. By means of a combination of a vacuum tube and an inductance in an associated circuit.

Q. 108. That is, you had this audion, which by the way was No. 2, was it?

A. Yes.

Q. 109. And also page 43 it is noted?

A. Yes.

Q. 110. And you put the plate circuit of that audion in series with the 250-volt shop circuit and with a heavy inductance?

A. Yes.

Q. 110a. And then what did you do?

A. The idea——

Q. 111. What did you do after you had done that?

A. I connected up a circuit so that the grid voltage could be suddenly varied and made negative so that the inductance would discharge suddenly.

Q. 112. Just a minute. Let us get this so that we all understand it. You are passing a current from the 250-volt shop circuit through the audion and through this heavy inductance and then you close a switch and that puts a certain voltage on the grid?

A. Yes.

Q. 113. What does that do to the main current?

A. That was a negative voltage placed on the grid which shut off suddenly the electron flow in the tube and this——

Q. 114. Just a minute, Mr. White. You put a negative voltage on the grid and made it impossible for electrons to cross that tube?

The Court: That is the purpose.

Mr. Davis: That is what they are trying to do.

Q. 115. There is energy stored in this inductance, is there not?

A. Yes.

Q. 116. That is, the iron of the transformer is charged with energy. It has to discharge itself somewhere?

A. Yes.

Q. 117. What did it do?

A. The energy stored in this inductance when released set up a very high voltage across the terminals of this inductance which discharges itself across a very small gap.

Mr. Davis: I think Dr. Langmuir has estimated what that was and I will not trouble you with it here.

Q. 118. I would like to bring out from the witness whether or not that strain was a strain on the tube?

A. Yes, this voltage set-up was very much higher than had been employed upon the tube during its exhaust or test.

Q. 119. I notice on page 46 an entry with reference to wiring up a 40,000-volt transformer, what was that, do you remember it?

A. Yes. Dr. Langmuir was very anxious to have work done on vacuum tubes in which plate voltages of the order of 10,000 and higher could be employed. At that time we had no convenient source of D. C. of this voltage and so we decided to use alternating current and this required a rather large and heavy transformer installation. I assisted in getting this up and wired up ready for use.

Q. 120. Did you have much to do with it afterwards?

A. No.

Q. 121. On page 63 there is an entry near the bottom of the page which I wish you would tell us about. First, tell us what the date is?

A. This entry on page 63 covered work between May 11th and May 17, 1913, and states that Mr. Alexanderson's idea of geometrical tuning using two audions had been made and referred to a report for further particulars.

Q. 122. Do you remember this test for geometrical tuning?

A. I do.

Q. 123. Was it successful or not?

A. Yes, it was successful.

Q. 124. What is this paper?

A. This paper which you hand me is my report on this test made in connection with Mr. Alexanderson's work.

Q. 125. The report is dated May 24, 1913. This particular copy does not appear to be signed by you but appears to be witnessed by whom and under what date?

A. It is witnessed by M. E. Christie, June 3, 1913, and by Dr. Whitney on September 25, 1913.

Mr. Davis: I imagine that a signed copy is in evidence in the other suit which was referred to before Judge Bodine. I offer this report in evidence.

(Received in evidence and marked "Plaintiff's Exhibit No. 173." *See Volume IV, Plaintiff's Exhibits, page 115.*)

Mr. Darby: Is that in connection with audion No. 2?

Mr. Davis: Yes, I should have brought that out. I will ask the question now.

By Mr. Davis:

Q. 126. Part of this report are four blueprints?

A. Yes.

Q. 127. At the foot of the first of the blueprints please read the last two lines.

A. "First audion No. 8, second audion No. 2."

Q. 128. What does that mean?

A. That means that on the above sketch the audion used in the first stage was No. 8 and the audion used in the second stage is No. 2.

Q. 129. And this report correctly describes, does it, the tests which were made at that time?

A. Yes.

Mr. Darby: I have no objection, but I submit I do not know how much additional evidence on the question of utility Mr. Davis is going to put in because the question of utility is not in issue.

Mr. Davis: I am not putting this in on the question of utility at all, this particular exhibit. If your Honor please, it is incidentally interesting as confirming Mr. Alexanderson's testimony, but what I am showing here is an audion No. 2, the first audion that was made with wire anode, which is exposed to this atrocious abuse of opening a 250 volt circuit through the primary of the transformer and which a few weeks later without any re-exhaust appears as a useful audion in one of these tests, again at 250 volts. It is to show that Dr. Langmuir knew how to exhaust audions.

Mr. Darby: I have no objection to that, but I will start objecting to every bit of evidence that is put in on the question of utility, being directed to an issue that is not involved.

By Mr. Davis:

Q. 130. Will you look at page 69? I think Dr. Langmuir has already referred to this page, which is the page in which he speaks of No. 2 as the only one which has shown this effect. I will ask you whether you remember these circumstances. Do you remember the entry and is it correct?

A. Yes, I remember the entry.

Q. 131. And is it correct?

A. Yes.

Q. 132. On page 149 under date of August 16th there are some tests described?

A. Yes, some tests are described using audion No. 2.

Q. 133. That is, were you testing audion No. 2 or what?

A. Using it as a tube to carry out certain other experiments.

Mr. Davis: You may cross-examine.

The Court: This is a good time for our short recess.

(Here a short recess was taken.)

(After a short recess.)

Mr. Haight: We desire to have the cross-examination of Mr. White, if there is to be any, deferred until Mr. Richmond can have an opportunity to look over his notebooks.

The Court: Is this satisfactory, Mr. Davis?

Mr. Davis: Yes, sir.

The Court: All right.

(Witness excused.)

Mr. Darby: Pursuant to the stipulation, if your Honor please, that was entered into today, it will take me just five minutes to read this portion of Mr. Waterman's testimony.

The Court: Which now has become and is read as part of the defendant's case?

Mr. Darby: Yes, sir. Frank N. Waterman under the stipulation, was a witness in behalf of the Marconi Company in a case which was identified as involving the Fleming Valve patent.

"By Mr. Hoguet:

Q. 18. Have you used, and are you familiar with the operation of detectors such as are illustrated in the Fleming patent in suit?

A. I am.

Q. 19. What was the structure of these detectors and where did you obtain them?

A. The detectors which I have used have also been furnished to me by the Marconi Company, and were the constructions ordinarily used in commercial practice. There have been two forms that I have used chiefly, one having the cylinder surrounding the filament, exactly as shown in the Fleming patent, and the other has one or two plates, located parallel to the filament. I have used both of these forms in considerable number; also a form in which the plate is used suspended immediately above or below the filament, according to which side up the lamp is used. These devices are excellent detectors. They vary in quality, as all such bulbs do. I found that a good bulb, one which performed satisfactorily, is equal to or somewhat superior to the best crystals, such, for instance, as cerusite crystal, which is the best crystal, the most sensitive crystal, which I am personally acquainted with. I have used these detectors in all the ordinary wireless telegraph circuits.

By The Court:

Q. 20. Were they made precisely in accordance with the drawings of the Fleming patent?

A. Some I think were literally like the Fleming patent with the exception possibly of the mode of staying the cylinder to keep it from rattling. I do not remember that I compared it in that respect. I have used considerable numbers in which there was the cylinder such as is shown surrounding the filament, in the manner shown. Others instead of having a complete cylinder, had two plates. Others had only one plate, and that sometimes parallel to the filament, and sometimes placed above or below it, according to which way we regard the lamp as hung."

Mr. Darby: The next is a portion of the answer to Q. 111:

". . . . I think I forgot to say yesterday that the action which Fleming was talking about was one which would take place to best advantage in a perfect vacuum, any space containing no gas whatever, because the electrons which Fleming referred to are derived from the filament. Now this molecular activity which DeForest speaks of throughout this patent, and the ionization, requires a gas as an indispensable requisite . . . ."

And the context of the remainder of the answer shows that this DeForest Patent No. 824,637, which is a patent different from the grid audion patent, No. 835,792—

"because the ions which DeForest employs are simply the electrified molecules of the gas, while the electrons which are referred to by Fleming and which constitute the active agent in the Fleming valve and in all of these incandescent lamp detectors, are electrons derived from the substance of the filament."

The next is part of the answer to Q. 120, and the context shows that he is referring to DeForest Patent No. 823,402:

"Everywhere throughout the patent, and there are seven places where I have noted where it is mentioned, it is a change of conductivity of a gas which is relied upon as the operating means, precisely as in the flame patents, and this is in sharp contrast to the explanation which DeForest found in the proceedings of the Royal Society for the operation of the Fleming device, where the conductivity is entirely independent of the presence of any gas whatever. It is due to electrons given off from the filament."

The next is part of answer to Q. 186:

"The action is, as Fleming stated, purely electronic, an action which gives us conductivity as the result of electrons emitted from the filament, and not as the result of any matter contained in the space surrounding the filament. That is the distinction."

And the next one is answer to Q. 195, and that is the last one:

"A. Yes; that is to say, you may adjust them at one potential of the local battery and show an increase, and another would show a decrease, upon receipt of signal. It can work extremely well in both cases. That is not apt to be a permanent condition, however. They usually decide what they will do, that they will do one or the other, and after they have been used for a few days, they permanently take a predilection to one way of working. That is another thing as to which there is no explanation at all. So that when I say I have no theories about this, I have, but they are note adequate. I am perfectly free to admit that. But one thing is very conclusively established, and that is that the action which takes place is an electron action just as Fleming said it was, and as most of the writers agree with this, and that is shown by the fact that the same action takes place exactly if we make bulbs which have what is now called the absolute vacuum which means a vacuum so high that no known test will reveal any attribute of gas.

Q. 196. Explain in this connection the relation of the electronic action of the device with the vacuum?

A. Well, in order that the electrons may have undisturbed passage across, it is necessary that there should not be too many gas molecules in the way. I am going in a minute to read what Fleming had to say about that, about the significance of the vacuum. If the vacuum is so high that the electron streams across from the filament to the plate are not seriously interfered with then the vacuum is sufficiently good for the purpose. But if there is very much gas present——"

Then there is an interruption by Mr. Bull with——

"Q. 197. What do you mean by very much?

A. I mean if a vacuum is not equal to a reasonably good incandescent lamp vacuum, for example, then the bulb gets freaky. It will work beautifully today and abominably, tomorrow, and pretty well the next day, perhaps, and its characteristics change with use. I have repeatedly taken characteristic curves of the same valve at successive periods and found that the shape varied very much, and such bulbs, on applying high pressure, showed at once that there was gas left in them to an obnoxious extent."

That was all of that part of the answer.

After Recess.

Mr. Davis: Now, Mr. White. If your Honor please, the examination which we have made of the records which defendants have given us, I am informed shows no record of any exhaust of any tube after the arrival of the molecular pump which Dr. Arnold testified arrived in the spring of the year 1913. I do not remember the exact date; and it is my understanding that I wish to have perfectly clear, that the defendants have given us all the records they have which are pertinent in this connection, and that they have no record of the exhaust of any tube after the arrival of that molecular pump.

Mr. Richmond: I will say that we have tried to find any such records, and have not succeeded in finding them.

WILLIAM C. WHITE, resumes the stand.

CROSS-EXAMINATION.

By MR. RICHMOND:

XQ. 134. In your notebook 452, which is Plaintiff's Exhibit No. 171, I find on page 34, a paragraph reading as follows:

> "In commencing tests for the day it was necessary to run filament for quite a time to get results consistent with previous day's results. At first results were five to ten per cent. high."

This refers to the audion that you have mentioned as No. 2, does it?

A. I believe it does.

XQ. 135. And the reason that you had to run the audion quite a time to get results consistent with the previous day's results, was because there was gas in the audion No. 2, was it?

A. Not that I believe.

XQ. 136. Well, then, what was the reason?

A. I think I have stated in my direct examination that it was the temperature effect due to probably expansion of some of the parts inside the tube.

XQ. 137. What parts?

A. The grid wires of this tube were very small in diameter, and were wound over a glass rectangle or rectangle made of a glass rod. The filament was relatively heavy, requiring about 2½ amperes, as I remember it, for heating; so that there was considerable heat energy dissipated from the filament. I believe that this heat energy warped the grid slightly so that the plate current or other characteristics changed during the first few moments of operation.

XQ. 138. Warped the grid wires, you mean?

A. I think that was the most likely explanation, yes.

XQ. 139. This time it was as much as five minutes, was it?

A. At this date, I cannot say, any more than remember it as a few minutes.

XQ. 140. I think it says five minutes on one of the small papers. I guess it was a card that has been offered in evidence as part of the records for audion No. 2; is not that true?

A. That is very possible.

XQ. 141. The date for the entry that I just read to you is Monday, March 17th, to Wednesday, March 19th, is it?

A. Yes, it signifies that that fact was noticed on tests conducted between those two dates.

XQ. 142. On page 232 of this same notebook under date of Monday, November 17th, to Saturday, November 22d, you wrote:

> "The perfectness of the vacuum in an audion can be told by the noises in the phone. Absolute quiet denotes a nearly perfect vacuum, slight frying some gas present, loud frying more gases, shrieking change of pitch with Eg and sharp clicking, poor vacuum, nearly at blue glow stage."

That is quoted correctly, is it?

A. Yes.

XQ. 143. And I do not remember that I gave the year for that.

A. 1913.

XQ. 144. And the statement is correct, is it?

A. I believe that the statement is correct provided there is no capacity resistance or inductance in the circuit which would otherwise account for the noises.

XQ. 145. Just explain a little more what you mean by that last statement.

A. There are a number of different circuit combinations in which a vacuum tube is employed that may cause variations in plate current, that will cause noise in a telephone receiver, through which the plate current passes. Inductance in the grid or plate circuit may cause oscillations; also combinations of resistance or capacity may cause noises. Under certain conditions noise is a good criteria of vacuum.

XQ. 146. And those other circuit conditions that may give noise give a sustained pure tone, do they?

A. Not necessarily. Particularly if there is any resistance and capacity in parts of the circuit you can get a charging up and discharging effect which may produce a series of clicks, a rattle or a rather strident musical note.

XQ. 147. When you were testing audion No. 2 within the dates Monday, March 17th to Wednesday, March 19th, which comprised the paragraph I have read, when I began the examination, you were not using one of those particular circuits that you mentioned, were you?

A. I believe in that particular paragraph I was taking data on characteristic curves. There is nothing in the notebook to indicate this, but that is my recollection.

XQ. 148. And you were not using one of those oscillatory circuits?

A. Not when that particular reference to five and ten per cent. variation in plate current is recorded, no.

XQ. 149. On page 35 of your notebook within the dates March 17th to March 19, 1913, I understand you wrote:

> "When filament is at about one ampere a low pitch sort of rattling is heard, as filament temperature is raised this raises in pitch until at about 1.3 amperes it is a sort of squeal."

Was that due to gas under the statement that you made on page 232 which I have just quoted to you?

A. I note the statement on page 35 at which the noise is referred to is preceded by sketch showing a circuit arrangement in which audion No. 2 was employed when this accoustic effect was heard. That circuit contains an inductance in the grid connection and a telephone receiver in the plate connection. With present-day knowledge it is very probable that this would set up oscillations.

XQ. 150. And those oscillations would depend in pitch on the magnitude of the filament current, would they?

A. It is difficult to state. They might.

XQ. 151. And they might also be due to gas, might they?

A. My reason for not believing that they were due to gas is because of the many uses to which I put this tube both before and after this test in which gas would have been indicated clearly. I believe that the circuit shown there, in view of present knowledge might easily cause oscillation.

XQ. 152. Will you please point this out?

Mr. Davis: I have no objection to it being marked but I suggest that it be marked in a way that clearly distinguishes it.

Mr. Richmond: I just asked Mr. Davis whether he had any objection to indicating points on the sketch with letters.

Mr. Davis: Perhaps the witness might use this red pencil.

Mr. Richmond: We will understand that his penciling is done only on the sketch of page 35 in this connection.

A. The sketch of this connection is preceded by a statement which reads as follows: "Tried to use No. 2 as a wireless receiver using a buzzer for sender. Could get no results." The sketch indicates that some form of antenna and coupling coil were used in an attempt to pick up the oscillations from the buzzer.

This sketch shows an inductance L in the grid circuit and a telephone receiver T in the plate circuit. This is the telephone in which the noises were heard. It is very possible that these two inductances in connection with the capacity between the grid and plate might set up oscillations and it is very possible that some of these noises were introduced into this system by the antenna which was a short length of wire in the room.

XQ. 153. I notice on page 252 of your notebook under the date December 22d to December 29, 1913, the paragraph reading as follows:

> "For patent reasons it is also desired to have a series of curves showing in every way possible the difference in action between the audion and the pliotron, the case of the detector pliotron will be taken up separately."

Will you please tell me just how those terms, audion and pliotron, are used there and explain what the paragraph means?

A. The audion referred to in that paragraph is the DeForest audion. That is the type of audion manufactured by DeForest at that time and sold and used under that name. By "pliotron" is meant devices of the type that I had been exhausting and testing under Dr. Langmuir's direction. You had better read the question again.

XQ. 154. I think perhaps I ought to apologize for asking you two questions in one. I want you to explain what the paragraph means?

A. As I remember, the Patent Department was investigating the pliotron, as we called our vacuum tube, and were anxious to get complete information on it and how it differed from the prior art. The last reference, speaking of the detector pliotron, referred to a special tube I had been working upon, which employed mercury amalgam, so that it operated as a detector on a little different principle than the high vacuum tube.

XQ. 155. That is the detector pliotron depended on gas, did it?

A. To the best of my knowledge it depended upon a very low pressure of mercury vapor, but it operated with a plate voltage between 150 and 250.

XQ. 156. When was it that the Patent Department began this investigation that you have mentioned?

A. I do not know.

XQ. 157. I understand that the General Electric UV-200 tube has gas in it, and depends on gas in its action, and that the General Electric UV-201 tube is a high vacuum tube that operates independently of gas; is that correct?

Mr. Davis: I am wondering what part of the direct examination relates to these tubes?

Mr. Richmond: The witness' testimony in the Interference record.

The Court: That has been my understanding, so far as I recall, that the cross-examination of any witness whether produced in the Interference case or not, is here restricted to the examination in chief here given.

Mr. Richmond: Very well. That distinction had not occurred to me.

The Court: I think that has been followed, so far as I know.

Mr. Richmond: That is all.

Mr. Davis: No re-direct.

(Witness excused.)

WILLIAM D. COOLIDGE.

William D. Coolidge, was called as a witness in rebuttal on behalf of the plaintiffs, and having been duly sworn, testified as follows:

Direct Examination.

By Mr. Davis:

Q. 1. You are Assistant Director of the General Electric Company Research Laboratory in Schenectady?

A. Yes, sir.

Q. 2. Since when?

A. Since the spring of 1908, as I remember it.

Q. 3. Nineteen hundred what?

A. 1908, as I remember it.

Q. 4. And how long have you been in the laboratory?

A. Since the fall of 1905.

Q. 5. Now, it has appeared in other testimony which you have given in this Court—and I do not want to take the time to go into it, that you did some work in connection with wrought tungsten; that is true, is it?

A. That is true.

Q. 6. When that work was well along, so that you had wrought tungsten available, what did you do with it; first, it was an incandescent lamp, was [illegible] not?

A. Yes, first as a filament of an incandescent lamp.

Q. 7. Now, I suppose nothing is ever through, but when you were well along with that, what did you next do with this wrought tungsten?

A. We used it as the target of an X-ray tube, and also as a material for contacts.

Q. 8. And by "target," you mean anode?

A. Yes.

Q. 9. What targets were then being used in X-ray tubes?

A. Targets for the most part, targets with platinum faces.

Q. 10. And made of what material?

A. Platinum. That is, usually copper with a facing of platinum, which might have been attached in many cases, and was in many cases attached first to a little disc of nickel, and then this nickel was in some way braised or soldered to a block of copper.

Q. 11. Was aluminum ever used?

A. Not so far as I know, Mr. Davis.

Q. 12. In the tube at all?

A. Yes, as a cathode, and as an auxiliary anode.

Q. 13. Well, what was the usual material of the cathode?

A. Aluminum.

Q. 14. And was there any means provided for heating the cathode?

A. No.

Q. 15. That is, we are dealing now with the old-fashioned X-ray tube?

A. Yes, sir.

Q. 16. Now, it has been already testified in this case, and we need not repeat it, that the tube operated by ionization, and also that as the tube operated, it tended to drive the gas in the walls and clean-up. You are familiar with that operation?

A. Yes, sir.

Q. 17. What was done when that happened?

A. Such tubes were usually provided with regulators, that is, the regulator consisted of a source of gas, which liberated either by the application of heat, usually by the application of heat.

Q. 18. And could that be continued indefinitely?

A. The gas could, of course be continuously admitted to the tube to raise the pressure, but the performance of the tube was not good after a certain time. It became, according to the language of the art, "cranky." This term meant that the tube was no longer stable; that is, the operator in using the tube had arranged the apparatus and the plate perhaps, if this was to be a radiograph, and expected when he closed a switch, to get, let us say, 30 milliamperes, for let us say one second at a certain voltage; but as a matter of fact, perhaps he got 30 milliamperes for one-hundredth of a second, and then no more current would pass through the tube. Under such conditions, the tube was spoken of as being a cranky tube.

Q. 19. Now, you spoke of using tungsten in the X-ray work. Did you mention the word "target"—yes, you did?

A. Yes.

Q. 20. Have you here among the exhibits, anything which will illustrate the target which you were speaking of?

A. Yes, the target in this tube here (indicating).

Q. 21. Just a moment, Doctor. Let me get the exhibit number—Plaintiff's Exhibit No. 48.

A. Is similar to the tungsten target which we developed and sold for use in the gas-filled X-ray tube to replace the targets which had been used prior to this time with a platinum face.

Q. 22. Now, when you say the target here, you are speaking of this copper mass, which is the most conspicuous mass inside the tube, are you?

A. Yes, sir, containing a little tungsten button.

Q. 23. And that button on the face of the target is tungsten?

A. Yes, and that receives the cathode ray bombardment, that little part there.

By The Court:

Q. 24. Yes, that is the target, the anti-cathode or anode?

A. Yes.

Q. 25. What I was about to ask, Mr. Davis, and really want to find out, is whether, in the old Crookes tube, the cathode was heated at all as it is in the Coolidge tube?

By Mr. Davis:

Q. 26. Will you answer that, Doctor?

A. The early Crookes tube had two electrodes, both of aluminum, a flat circular plate, as I recall it, as a cathode, and then either a little wire or ring, as I remember it, serving as an anode, the anode in that case being placed at one side of the tube axis. The cathode rays then coming from the cathode in the early Crookes tube went the length of the tube, and there collided with the glass wall of the tube, causing this beautiful green fluorescence, and of course there producing X-rays, although that was not known until later that X-rays were produced where the cathode rays collided with the glass wall of the tube, or with any other body that Crookes may have placed inside the tube in the path of the cathode rays.

Q. 27. That is, a cathode ray striking anything is apt to produce an X-ray, is that it, Doctor?

A. It does produce X-rays.

Q. 28. I do not think you have answered his Honor's question.

The Court: As I understand, in the Coolidge X-ray tube, the cathode is a wire as it is in the radio bulb?

Mr. Davis: Yes, sir.

The Court: Which is heated in order to cause the electrons to boil off, so to speak; but as I understood in the old Crookes tubes, that is, I have gathered from the evidence here, that a cathode was a solid mass of metal in the old Crookes tube, and was not a wire or filament that could be heated, and that the heat in the inside was the result of the bombardment and operative to that extent on a different principle from this tube.

By Mr. Davis:

Q. 29. That statement is corrected, is it not?

A. That is correct, your Honor. The mechanism of the emission of the electrons from the cathode was an entirely different mechanism. There was gas in the tube, the gas was ionized, and then under the influence of the electric field, positive ions were driven against the cathode, and there caused the electron emission.

The Court: In short, maybe I can express it this way—the old Crookes tube did not use the Edison effect, or start with the Edison effect?

The Witness: Did not use it.

The Court: And your tube does?

The Witness: Yes, sir.

Q. 30. It is a very accurate statement, is it not, Doctor, that there was no Edison effect in the old tube?

A. No, sir; there was no Edison effect in the old tube.

Q. 31. But the old tube is what was sometimes called a "self-sustaining discharge," was it not?

A. Yes, sir.

Q. 32. Which means a discharge sustained by the ionization in the tube?

A. That is correct.

Mr. Davis: Or perhaps more properly put, the conditions necessary to the discharge.

The Court: Yes, I think I have that now.

Q. 33. Now, did you or did you not, put this tungsten target embedded in copper on the market?

A. Yes, that was put on the market.

Q. 34. About what time?

A. As I recall, that was late in 1911.

Q. 35. Do you remember—and I think you have also testified to that in this Court—something about ordering an X-ray set?

A. Yes, sir. In connection with the development of this copper-backed tungsten target, it became necessary for us to do some experimental work on the X-ray tube. That is, for us to abuse the target as much as we could, so as to find, by experiment, a design of target which would stand the most punishment, and I did go to Philadelphia to order a so-called ten-milowatt snook machine for this purpose.

Q. 36. Doctor, you have not said something because it is so obvious to you. What is the strain, what is the abuse put upon a target? What does it have to stand?

A. The cathode ray stream in the X-ray tube is all concentrated in this case on the little tungsten button in the target. If I may go back one step, all of the electrical energy delivered, may I change that, because that would not apply to the tubes in which these tungsten targets were first used?

Q. 37. You are speaking now of the old X-ray tube?

A. Yes.

Q. 38. With your tungsten ~~target, if~~ you please?

A. Yes. And in those tubes a very large fraction of the electrical energy delivered to the tube terminals was put into kinetic energy of the moving electrons in the cathode ray stream and as these rapidly moving electrons collided with the target, two things happened; something like 99.9 per cent. of the energy of the rapidly moving particles was changed into heat delivered to the target and the other perhaps one-tenth of 1 per cent. went into the production of X-rays.

Q. 39. What is the difference between that and what we have spoken of in this case as heating the anode by bombardment?

A. In this case we are heating the anode, in the case that you speak of, we are heating the anode by cathode ray bombardment. We are not doing it in a very high vacuum. As I have already said——

Q. 40. Just for the moment I am trying to show or to bring out—we have talked in this case a great deal about electron bombardment of anodes and it has been testified that that heated the anode. Just thinking of that bombardment, is that any different from what you are talking about; in character, I mean?

A. No, sir.

Q. 41. There is, however, one difference that I would like to bring out and that is, will you discuss what you call the focal spot in the anode?

A. The focal spot is the area on the target on which the cathode rays are all made to impinge.

Q. 42. Why is it necessary that there should be a limited spot like that?

A. If the tube is intended for medical diagnostic use the size of that spot becomes very important because the X-rays are in that case to be used to produce a shadow picture and the sharpness of the shadows will be determined by the size of the focal spot and of course by the geometry of the thing.

Q. 43. Let us stop there and be sure we have made that clear.

The Court: Is that spot then like the shutter of the camera?

Mr. Davis: It is more like the source of light. You are very careful to have the source of light in a projector, a moving picture projector or automobile headlight, you are careful to have a small source of light because if you had a large source of light your beam would not be a straight beam but a ragged beam.

Q. 44. From the X-ray point of view, Doctor, could you compare this focal spot with the source of light?

A. Yes.

Q. 45. The X-rays come from all over this spot?

A. Yes.

Q. 46. You think of a shadow of an object coming from light coming from a point and you can draw a line from that point to the object and you would get a perfectly clear shadow, but if you had two points and drew lines from those two points through the object to the table under the object, then you got two different shadows differently located?

> The Court: If I understand it, I know very little more about cameras than I do about X-rays, but as I understand it, the more you close a shutter through which the light passes, the sharper a photograph you get on your plate, and I am wondering whether the smaller the area upon the anode in an X-ray tube upon which the cathode rays impinge, the better shadow graph you get as the result of the use of your X-ray tube.

Q. 47. Is that right, Doctor?

A. Yes. There is this objection to the case of the diaphragm in the camera, perhaps an objection to the comparison in that one of the functions of the diaphragm in the camera is to limit the portion of the lens which is used. The lens is not well corrected if you use a very large aperture. It is much more like the case which Mr. Davis mentions of the projection lantern where you use as a source of light for projecting a picture on the screen as small a source as you can get, as nearly a point source as possible. With the arc lamp that was very easy. You could use the tiny hot spot on the carbon. With the incandescent lamp, special lamps have been developed with that point in mind of getting the light from just as small an area as possible, so that there will be as little penumbra around the shadow as possible.

Q. 48. When you speak of abusing a target, you mean heating it by the cathode stream?

A. Yes. It is possible in the X-ray tube where you have by the construction of the tube limited the size of the focal spot to something definite, it is then possible to pass a great deal of energy through that tube if you will. So much so if you like that you will melt and vaporize any material that you put there at the surface of the target. There is such a concentration of energy.

In the case of the X-ray tube built for medical diagnostic work, you make that focal spot small enough so that under the conditions in which the doctor uses the tube the shadow of the bones, let us say, or other objects in the body shall be sufficiently sharp for the purpose, but on the other hand you must not make the focal spot too small, because if you do it will then not be possible to use sufficient energy so as to get sufficient X-ray intensity to make the picture in a reasonable time, in a time during which the patient or moving organs inside of the body can remain stationary.

I might add just one word to that. You use a tungsten target or a copper block containing a button of tungsten because of the high melting point of tungsten and the low vapor pressure which will then let you with a given amount of energy make that focal spot just as small as possible. That is, you will always use at that point, the element having as high a melting point and as low a vapor pressure as you can get hold of and you are also interested in the heat conductivity of that material, as the higher the conductivity of that material the faster heat can flow away from that spot.

Q. 49. And about when did you receive this X-ray outfit? I do not care for the exact date.

A. I think it was late in 1911, either late in 1911 or early in 1912.

Q. 50. When it came did you put it into use?

A. Yes.

Q. 51. Testing the targets which you made and so forth?

A. Yes.

Q. 52. What is this book?

A. That is my notebook, beginning with August 25, 1911, and extending to and through December 20, 1912.

Q. 53. And this was one of the regular laboratory notebooks kept by you in the course of your employment?

A. Yes, sir.

Q. 54. And the statements therein contained were correct to the best of your knowledge and belief at the time you made them?

A. Yes, sir.

> THE COURT: Before you go into that, may I ask one question to make sure that I am right? Is cathode ray bombardment synonymous with electron bombardment?

Q. 55. Is that right?

A. Yes, cathode rays are rapidly moving streams of electrons.

Q. 56. I think that that expression cathode ray bombardment is a rather old expression and we now speak of it as electrons.

A. Yes. We now say that, as far as we know, electrons are all alike no matter what their source is. At present we use the term cathode rays for high speed electrons in a tube, or coming from a tube, and beta rays for exactly the same thing, when the rays come from radio active matter.

MR. DAVIS: I offer the notebook in evidence.

(Received in evidence and marked "Plaintiff's Exhibit No. 174." *See Volume IV, Plaintiff's Exhibits, page 121.*)

Q. 57. I ask you to look at pages 171 and 172. What is the date of the entry beginning four or five lines down on page 171?

A. May 8, 1912.

Q. 58. Without taking the trouble to read that entry, will you explain it and tell what happened as recorded there on those two pages?

A. I say in this entry that I have received tube No. 594,036, from Wiggin. Mr. Wiggin was of the firm of McAllister & Wiggin in Boston. They were X-ray tube manufacturers and I had sent to Mr. Wiggin a tungsten anode, that is, an all tungsten anode and a dished, concave, tungsten disc to be used as a cathode.

I had had trouble prior to this with the melting of aluminum cathodes when I had operated tubes with a great deal of current and so had been anxious to try tungsten cathodes. This was my first opportunity to do it. This tube had been built for me by Wiggin in Boston. He reported to me——

By Mr. Davis:

Q. 59. You had a tube there which had two electrodes, both tungsten?

A. Yes, sir.

Q. 60. And they were both cupped, or not?

A. I think not, Mr. Davis.

Q. 61. Never mind, Doctor. It is not important, perhaps. The records show there that the tube was very cranky; is that right?

A. Yes.

Q. 62. Why was that tube cranky compared to an ordinary tube?

A. Because the tungsten cathode contained so little gas.

Q. 63. Is that the nature of wrought tungsten?

A. Yes, I would say so, because of the method of preparation used.

Q. 64. But you finally got that tube going?

A. By an artifice, yes, sir.

Q. 65. The artifice consisting of introducing gas from this gas-producing arrangement?

A. Yes, sir. Repeatedly introducing gas and operating the tube with high voltage.

Q. 66. And you finally got it going very well?

A. Yes.

Q. 67. And how did it run, that is, what were the circumstances or method of operation?

A. The cathode became strongly heated and then the tube ran very steadily.

Q. 68. What heated the cathode?

A. Positive ion bombardment.

Q. 69. On pages 173, 174 and 175 appear notes and suggestions of Dr. Coolidge to use a hot cathode in an X-ray tube.

The Court: What date is this?

Mr. Davis: May, 1912. I am not trying to prove any earlier date than we pleaded. I want to show the facts. As has been suggested, this perhaps may be immaterial and I will just call attention to these pages that mention this suggestion.

The Court: Does that mean to heat the cathode by external heat?

By Mr. Davis:

Q. 70. The cathode was heated how in this experiment?

A. Only by positive ion bombardment.

Q. 71. Was this a practical tube?

A. I should say not. It certainly was not a very convenient tube to handle as it was quite an art to get it started.

Q. 72. I notice the suggestion at the bottom of page 175 to have a tungsten cathode wound on a sort of spool made of what?

A. I think made of fused alumina or fused silica.

Q. 73. Would that as you now know have been possible?

A. It would certainly not have been an operative tube. That is, it would not have been a pure electron discharge tube.

Q. 74. At the end of all this it says, somewhere near the end it says: "I will do this tomorrow." Did you do it tomorrow?

A. No, sir.

Q. 75. Now, I call your attention to page 266 and ask you if you will describe that experiment. First, what is the day on which this experiment was made?

A. This experiment was made on September 24, 1912.

Q. 76. What was the experiment?

A. In this tube we had a tungsten cathode and a heavy tungsten anode, that is, both cathode and anode were tungsten. The tube——

Q. 77. Was there or was there not any means of heating the cathode externally?

A. No.

Q. 78. And it was a gas tube, was it?

A. It was a gas tube.

Q. 79. And you ran that tube with those two electrodes both of tungsten?

A. Yes.

Q. 80. Now, will you read the paragraph beginning "One effect"?

A. "One effect shows up clearly. Starting with a vacuum of say 20 microns the tube runs O. K. The electrodes both heat up strongly and there is a white hot focus spot on both cathode and anode."

Q. 81. Why was there a white hot focus spot on the cathode?

A. The cathode was heated by positive ion bombardment and there was a strong focusing action of the positive ions causing their bombardment to take place over a very limited area on the cathode.

Q. 82. Will you continue, please, reading that extract?

A. "The pump was running all the time but it was arranged so that by means of mercury the connection between the tube and the pump could be broken."

Q. 83. So now if the pump is turned on it means that you connect the tube with the pump and start the pump?

A. That is it. "Now, if the pump is turned on and the current kept on so as not to let the electrodes cool off"—by the current I mean the high voltage current passing through the X-ray tube—"the resistance of the tube quickly rises to a point where no more current will pass."

Q. 84. Just say in your own words what happened. You had this old-fashioned X-ray tube running with the cathode hot and the anode hot, each heated by bombardment from the other. You were running the tube along and what happened?

A. Suddenly it stopped carrying current.

Q. 85. Now, please read the rest of the paragraph.

A. "This shows pretty clearly that having a white hot spot at the active part of the cathode, does not even with the potential necessary for an eight-inch spark gap free electrons enough out of the cathode to hold down the resistance."

Q. 86. What does it mean, the potential of an eight-inch spark gap?

A. The potential was in this case being measured in what was then a customary manner for doing it in X-ray work by means of a spark gap, connected in parallel with the tube. That is, this spark gap consisted of a pair of pointed metal electrodes, the distance between which was easily regulatable from a distance, and the method of using the device was to simply, while the tube was running, bring these points closer and closer together until finally the high tension discharge took the path between the terminals of the spark gap rather than going through the tube.

Q. 87. Was that high or low voltage in those days for X-ray?

A. That was nearly as high voltage as was used on X-ray tubes at that time.

Q. 88. What did you conclude from this experiment?

A. It made it look to me as though we did not get electrons from hot tungsten in a good vacuum.

Q. 89. Is that your view today?

A. No, sir.

Q. 90. Then you must have deceived yourself in some way in this experiment. Will you please explain your present view and why you were deceived?

A. I think that as the vacuum improved after establishing the connection between the tube and the pump, the positive ion bombardment sank to such a low value that the temperature of the cathode very rapidly fell to a point where no more electron emission from the cathode took place.

(After a short recess.)

Q. 91. So as the vacuum got higher in the operation of this tube, what happened to the temperature of the cathode?

A. The temperature of the cathode sank very rapidly.

Q. 92. In layman's language, the cathode cooled off?

A. That is right.

Q. 93. Why did you not see it cool off?

A. I probably did see it cool off, but not until the high tension discharge had stopped; that is, that cooling off would have been such a very rapid process; that is, you must bear in mind that the very hot spot in the centre of the cathode where the positive ions were focused was a very tiny area and that the balance of the cathode, the surrounding metal, was probably only at red heat so that it would take a very small fraction of a second, a very small fraction indeed, when the positive ion bombardment ceased, for the temperature of that central very hot spot to sink to essentially that of the surrounding metal.

Q. 94. Was it a thing that you could conveniently and safely observe anyway?

A. Not as conveniently as one would observe in an incandescent lamp, because of the need of protecting oneself from the X-rays.

Q. 95. How cool would that hot spot on the cathode have to be, looking at it from the present knowledge, not what you knew then, to make it stop giving out electrons sufficient to maintain that tube in action?

A. It would still be very hot; let us say a little below 2000 degrees Centigrade.

Q. 96. You are talking Centigrade?

A. Yes.

Q. 97. We speak of the expression white hot. What do you call white hot in Centigrade?

A. That is a matter of definition. I would call melted iron white hot, at 1600 degrees more or less, depending on its purity.

Q. 98. Centigrade?

A. Yes.

Q. 99. Did you understand what was going on at the time this experiment was made?

A. No, sir.

Q. 100. What was the next thing that you did or the next discussion that you had in connection with an X-ray tube having hot cathodes?

A. That was a talk which I had with Langmuir, at which interview Dr. Langmuir told me about his pure electron discharge work.

Q. 101. What did he tell you in substance?

A. That he had found that——

Mr. Haight: May we have the date fixed for that?

Mr. Davis: I will fix the date. Do you want it fixed at this moment?

Q. 102. Doctor, if you will look at your notebook, page 325, it may be that gives the date?

A. December 10, 1912, I find an entry therein concerning this interview with Dr. Langmuir.

Q. 103. Now, what did Dr. Langmuir tell you at that interview?

A. That when these filaments had been carefully freed from gas in a high vacuum, he had found it possible to maintain a discharge, a pure electron discharge, from a hot filament, that the electron emission had instead of decreasing with the removal of gas from the tungsten filament, which was to be used as a cathode, had increased up to a certain point, and from there on it remained steady, and that this was a thoroughly reproducible condition.

Q. 104. You spoke about filaments. Were there more than one filament?

A. Two filaments.

Q. 105. What were they?

A. Of tungsten.

Q. 106. And how were they used respectively?

A. One was heated by the passage of current through it, and then the negative end of a circuit of a couple of hundred volts, as I remember it, was connected to the hot filament, and the cold filament was connected to the positive end of the circuit.

Q. 107. And you said that Dr. Langmuir spoke of having removed gas from these filaments or some such expression; did he tell you how he did it?

A. Yes, sir.

Q. 108. What was it?

A. By heating these filaments very hot in a very good vacuum.

Q. 109. Were you or not familiar with any work which Dr. Langmuir had been doing up to that time in connection with high vacuum?

A. Yes.

Q. 110. To what extent were you familiar with it.

A. I was very familiar with it.

Q. 111. What was the character of that work?

A. It was of a very high quality——

Mr. Haight: I object to the characterization of the witness in that way, and I would like to have your Honor admonish Dr. Coolidge that he must speak of his own knowledge.

Mr. Davis: I am asking of his own knowledge.

The Court: Yes.

Mr. Davis: I want to be quite sure that the last few answers were what Dr. Langmuir told him.

The Court: Yes, but it is this answer that Judge Haight is speaking about, and I think that answer should so far be stricken out and the question repeated, because I think Dr. Coolidge did not have in mind the limitations of his answer when he began.

(Discussion.)

By Mr. Davis:

Q. 112-13. What was the quality of the equipment which Dr. Langmuir had in his laboratory, so far as it had to do with vacuum work at that time?

Mr. Haight: I object to that. He can tell what the equipment was, but not characterize the quality.

The Court: I think that objection is good.

(Discussion.)

By Mr. Davis:

Q. 114. What did you do next, Dr. Coolidge, after this talk with Dr. Langmuir?

The Court: Do not understand, Mr. Davis, that you cannot have this witness tell all the facts that you want about the equipment.

Mr. Davis: If your Honor please, I think that Dr. Langmuir has described the equipment.

Mr. Haight: I will save time by saying that we do not question the fact that the equipment that Dr. Langmuir says he had, was there, nor so far as I know, is there any intention on the part of the defendant to question the fact that that equipment was adequate for the purposes for which Dr. Langmuir says he used it.

Mr. Davis: That is not exactly what I want.

Mr. Haight: Tell me what you want, and maybe I can give you that. Perhaps you had better let Mr. Richardson go into that.

Mr. Davis: I think I will pass the question, if your Honor please.

By Mr. Davis:

Q. 115. Dr. Coolidge, will you tell us what you did next in connection with those X-ray tubes, after this talk with Dr. Langmuir?

A. Dr. Langmuir suggested to me in the talk that I try such a pure electron discharge in an X-ray tube, and we immediately got busy and tried it out.

Q. 116. What was the type of anode with which you began your experiments?

A. It consisted of a circular disc of tungsten, perhaps an inch and a quarter or so in diameter, supported by means of a tungsten stem, and the disc was perhaps, as I remember it, perhaps 20 or 30 mils (twenty or thirty thousandths of an inch) thick.

Q. 117. I show you a copy of the patent drawing on page 2432 of the Interference record, being the drawing of the Coolidge patent, No. 1,203,495; is the anode shown in Figure 1 of that patent anything like what you are now describing?

A. Yes, Mr. Davis, except that in the first tubes the tungsten disc was mounted at right angles to the supporting stem, instead of being inclined at an angle of 45 degrees, as shown in that drawing.

Q. 118. What were the limitations of this anode?

A. I am not sure that I understand your question, Mr. Davis, but if you refer to the amount of energy which could be dissipated in such an anode, I will say that because of its thinness, it proved to be easy to melt holes which went right through it where the focal spot was, as small as it was, in some of these experiments.

Q. 119. Did that impose or not, any limitation on the output of the tube?

A. It did.

Q. 120. Would the tube with such anode otherwise be useful for any purpose?

A. Yes. After the tube had been developed to a certain stage, that is, where the design was right, and where the vacuum was sufficiently good and the electrodes sufficiently freed from gas, so that the tube was stable, it could have been used very nicely for medical diagnostic work or even for medical superficial therapy.

Q. 121. How long did it take you to do all these things, Doctor?

A. The work, I should say, was very encouraging after we had been—the tube I should say was very encouraging after we had been working on it for perhaps two months.

Q. 122. Now, how much effort and energy was put on the tube work during those two months?

A. A great deal. I had an assistant, Mr. Leonard Dempter, who worked with me, and during that time we were both putting in nearly all of our time into that work.

Q. 123. Now, why did not you use that large copper-backed tungsten target which you have shown us, and which you were then selling?

A. Because I did not know how to get the gas out of the copper.

Q. 124. Would it or not have made a tube having more utilities?

A. Yes.

Q. 125. Did you or did you not ultimately find out how to get your gas out of that copper?

A. Yes.

Q. 126. And then put out tubes with the copper anode, such as this tube, Plaintiff's Exhibit No. 48?

A. Yes, we did.

Q. 127. You also developed a special anode later of tungsten, did you?

A. Not later, Mr. Davis, than the development of this radiator type of tube, but later, than the experimental work on these first hot cathode X-ray tubes, with the thin targets.

Q. 128. I show you Plaintiff's Exhibit No. 42; that large mass of tungsten in the middle is what you are talking about, Doctor, is it?

A. Yes.

Q. 129. What is that?

A. That is a mass of wrought tungsten attached to a stem of wrought molybdenum.

THE COURT: Why is the face that face?

Q. 130. Why is the face cut off at an angle, Doctor?

A. It is convenient for the Doctor using the tube to have his patient placed in many cases horizontally with the photographic film underneath, and then the tube placed over it in this position.

Q. 131. That is horizontal?

A. Horizontal.

Q. 132. With the——

A. With the focal spot looking down.

Q. 133. And that will throw the X-rays down, will it?

A. The X-rays come from the focal spot in all directions, but it is better not to take them off at too nearly glancing incidence, because of interference from the roughness at the focal spot. For that reason, the 45 degree angle has come into common use.

Q. 134. And when you came to sell the tubes commercially, Doctor, the first tube sold commercially, had which anode?

A. They had a massive tungsten anode like the one in this tube.

Q. 135. Which is Plaintiff's Exhibit No. 42. What is this book I hand you?

A. That is my laboratory notebook covering the period from December 23, 1912, to August 25, 1914.

MR. DAVIS: Now, if your Honor please, I am going to suggest that I offer in evidence such pages of this notebook as can be agreed upon, that is, all pages which are relevant to this inquiry, up to the day on which Dr. Coolidge filed his application for the patent on the X-ray tube, and those extracts be given an exhibit number, and I fancy there will be no trouble going over the book with defendant's counsel.

Mr. Haight: I understand that that is vouched for by Dr. Coolidge?

Mr. Davis: It is another book. This is the second book. I offered the first one.

The Court: This one has now to be shown—the last question was directed to this book, was it not?

Mr. Davis: Yes.

Q. 136. I have not asked him whether the entries are correct, and now do so?

A. Yes, Mr. Davis, to the best of my knowledge and belief.

Mr. Davis: I offer in evidence the selected pages of this book to be supplied.

Mr. Darby: Do I understand that you offer this book up to the filing date of the Langmuir patent or Coolidge patent?

Mr. Davis: Coolidge.

Mr. Darby: I should think, but I do not know——

Mr. Davis: I am perfectly willing that my brother should inspect it up to the filing date of Langmuir, if he wants to.

Mr. Darby: I think I would like to.

The Court: All right. The pages to be supplied will now be given a number.

(Received in evidence and marked "Plaintiff's Exhibit No. 175." *See Volume IV, Plaintiff's Exhibits, page 128.*)

Q. 137. Will you tell me the date of the work recorded on page 59 of this last notebook?

A. February 17, 1913.

Q. 138. What was the character of that work, was it still working on that tube on the hot cathode X-ray tube?

A. Yes.

Q. 139. Now, will you read the paragraphs beginning from the very first?

A. "Work with tube 112"?

Q. 140. No. I mean the paragraph beginning with the words, "From the very first."

A. (Reading):

> "From the very first turning on of the current, this tube has focussed sharply. As a result, it has been easy to heat the target so as to get the gas out of it. The tube was therefore in excellent condition after perhaps one hour's work on it, after it had come out of the oven."

Q. 141. Go on.

A. (Reading):

> "The electrodes were fresh ones, so this experiment demonstrated conclusively that the target has been the troublesome source of gas, and the lack of focussing, when running as an ordinary tube, that is, before getting the ordinary vacuum, has been what has made the tube exhaust so tedious and precarious."

Q. 142. In a very few words, Doctor, what was the nature of the difficulties that you had been experiencing up to that time?

A. We had cracked and punctured tubes, due to local heating of the glass, which had come from faulty design, and from our operating the tube while the vacuum was too bad. That is, not waiting long enough for the pumps.

Q. 143. When you say "faulty design," do you mean it was a design which you regarded as faulty before?

A. No, sir. Which we had found bad in the course of these experiments or which we found bad in the course of these experiments.

Q. 144. Did you have any trouble getting the gas out of the electrodes?

A. We had a great deal of trouble; if the tube was operated while the vacuum was too poor, the glass which supported the cathode structure was bombarded and liberated gas. This, of course, increased the gas pressure in the tube, and hence the positive ion bombardment, and we had a more or less run-away effect, and in the first place——

Q. 145. I am not sure that is clear. I would like to be very sure that is clear. Your cathode bombardment heated what?

A. The glass tube supporting the cathode structure: that is, the positive ions are directed by the electric force towards the cathode end of the tube, and with the early designs which we used, these positive ions would bombard the glass support to the cathode.

Q. 146. That is, during the exhaust, Doctor, you are talking about, now?

A. During the exhaust, and by their bombardment would liberate from that glass more gas, and that meant more ionization. Therefore, more positive ion bombardment, and therefore more gas, so that our exhaust time was erroneously increased by that difficulty, and by our failure at the time to fully understand the source of the difficulty. Besides this, we had troubles from the——

Q. 147. Just a minute there, Doctor. There are some records in this book of puncturing the glass. Will you explain that in this connection?

A. Yes. The same positive ion bombardment to which I have alluded, did cause local heating of the glass envelop behind and in the neighborhood of the cathode, and that local heating gave rise to cracks and so-called punctures.

Q. 148. That is actually melting a hole through the glass, is it?

A. The hole is usually melted through after the crack has taken place. The electrical discharge then goes through as the air rushes in, and by its heat, causes a melting of the glass.

Q. 149. Will you go on and continue what you were saying when I interrupted you?

A. We had this trouble frequently, that the high tension discharge instead of confining itself to the tube—and bear in mind, please, that the tube was in these early experiments connected to the pump system—the electrical discharge instead of confining itself to the tube, would often go down this connecting tube towards the pump and puncture the glass connecting tube.

Q. 150. What pump did you use in the beginning of your work?

A. The rotary oil pump, such as used in the incandescent lamp exhaust.

Q. 151. And between that pump and the tube, what did you have?

A. A liquid air trap.

Q. 152. And was that pump of sufficiently high capacity to suit you?

A. It did not give a sufficiently high vacuum.

Q. 153. What did you do?

A. I acquired a Toepler pump.

Q. 154. Does that give the high vacuum?

A. It gave the high vacuum.

Q. 155. Was its capacity sufficient?

A. It is a very slow-acting pump. As I used it, it was operated by hand, and it also made the exhaust operation much more lengthy and tedious than it would otherwise have been.

Q. 156. Speaking of the length of these exhaust operations, were you talking of minutes or hours?

A. No. Usually days.

Q. 157. A matter of several days, was it?

A. Yes.

Q. 158. In this early work?

A. It might be several days.

Q. 159. What if any further pump did you acquire for this work?

A. At one time I acquired the Gaede mercury pump, that is, a rotary pump, and still later a Gaede molecular pump.

Q. 160. Now, Doctor, will you speak a little of the experience which you had of the action of the ions on the filamentary cathode during this work?

A. Yes, sir. From the beginning, we were considerably troubled by that. The vacuum not being good enough at the time—positive ions would bombard the cathode, and would thereby raise its temperature, and in that way increase the electron emission, and this would result in great instability of the tube. We experienced this difficulty in the very beginning, and felt that it was vital to study it, so that we used not only an ammeter to measure the current for heating cathode filaments, but also used a voltmeter connected in parallel with the cathode filament.

Q. 161. Now, just a moment. That gives you the resistance?

A. Yes.

Q. 162. And therefore the temperature of the filament?

A. Yes.

Q. 163. Doctor, did you have this difficulty only with the oil pump?

A. No, we had this difficulty for a long time, even after we had acquired the Toepler pump.

Q. 164. Did you find that there was any particular technique of exhaust as to the rate at which you could go forward and the rate at which you could put current on and so forth?

A. Yes. We found in the course of time that the thing to do was to go very slowly, increasing the amount of energy supplied to the tube, giving more time for the pumps to take the gas.

Q. 165. Now, when was it when you first put your tube into actual use outside of the laboratory? I do not care for the exact date, but was it during that year?

A. Very late in 1912.

Q. 166. 1913, was it not, Doctor?

A. Excuse me, it was very late in 1913. I think in December of 1913.

Q. 167. And from then on the exploitation was rapid or not?

A. I would call it pretty rapid, yes.

Q. 168. That is all I care for there. Do you remember filing a patent application for your tube?

A. Yes.

Q. 169. That is the Patent 1,203,495, which is in the Interference record and the history of the file wrapper and contents, is Defendant's Exhibit 67 the application as filed contained twenty-six claims. Some of the claims have to do with the focusing shield. In a word, what is a focusing shield?

A. It is the piece of metal used to so shape the electric field about the cathode as to cause the cathode rays to converge on a small area on the target.

Mr. Haight: The cathode in this Exhibit 42 is the larger piece of metal.

The Witness: No, this one here.

Mr. Haight: The disc.

The Witness: It consists of a little tungsten spiral placed within the molybdenum cylinder to the back of which a circular molybdenum disc is attached.

Mr. Haight: Now, where is the shield?

The Witness: That disc functions somewhat as a shield to protect the glass support to the cathode during the early stages of the exhaust.

Mr. Howson: You mean the focusing shield?

Mr. Haight: Yes.

The Witness: The member which has most to do with the focusing is the little cylinder of molybdenum in which the tungsten spiral is placed.

Mr. Davis: Let me refer to Exhibit 45 in which the focusing shield is removed and the spiral is exposed.

Mr. Haight: I see. Thank you.

By **Mr. Davis:**

Q. 170. The focusing shield, or at least an early form of focusing shield is shown in Figure 2 of the patent to which I have just been referring, is it?

A. That is correct.

Q. 171. And also 11 in Figure 1?

A. That is correct.

Mr. Davis: There, if your Honor please, is the gun barrel type at 11 in Figure 1. Other claims are specifically restricted to an X-ray tube, I want to call the witness's attention to two claims which are not so restricted.

By **Mr. Davis:**

Q. 172. I read you claim 3 of the application as filed:

"An electrical vacuum discharge tube, comprising an envelope and cooperating electrodes therein, at least part of one of which is adapted to be maintained at incandescence, the vacuum

> within said envelope being so high that the cathode is not sensibly heated by discharge current through the tube."

It does not appear on its face to be limited to an X-ray tube. Did you or not at the time you signed the application believe that this claim was broad enough to cover the tubes which Dr. Langmuir had disclosed to you in December, 1912?

A. No, sir. If I had I certainly would not have signed the application until that claim had been taken off.

Q. 173. Can you state what there was about that claim which led you to think that it referred to your work rather than to that of Dr. Langmuir?

A. I think that it must have been reference to the heating of the cathode. As I had already explained, I had a great deal of trouble from the heating of the cathode, in the experimental tubes, by positive ion bombardment. That positive ion bombardment was focused upon the little tungsten spiral and so constituted a source of instability if it existed.

Q. 174. Claim 9 of the application as filed read:

> "The combination of an envelope, cooperating electrodes therein, said envelope being evacuated to such degree that the mean free path between the residual gas molecules is greater than the distance between the electrodes, a source of energy connected to said electrodes, and means for heating at least part of the negative electrode to incandescence."

At the time that you executed this application, did you or did you not believe that this claim was broad enough to cover anything which Dr. Langmuir had disclosed to you in December?

A. I certainly could not have believed that it was broad enough to cover it, otherwise I would not have executed the application.

Q. 175. I hand you the claim and will you please explain what it was as far as you know that it led you to the belief that it referred to your work and not that of Dr. Langmuir?

A. I believe that it must have been this fact that in the——

Mr. Haight: May I suggest that possibly this kind of conjecture is in the same category that your Honor rather depricated while we were examining Dr. Arnold as to the reasons why he answered so and so or something or another of that effect, in the former proceeding.

Mr. Davis: I offer the statement that he may cross-examine him as much as he pleases.

Mr. Haight: I do not think I can really object. I suppose the witness may conjecture but I do not think it is of any weight.

(Discussion.)

The Court: That is different. If the testimony is predicated on knowledge or refreshed memory, all right, but not predicated on reason. I am not sure technically that even that would be admissible, but at the same time in the absence of objection it may be given.

By **Mr. Davis**:

Q. 176. Will you then answer the question?

A. I think it must have been due to the fact that I knew——

The Court: I am afraid, Dr. Coolidge, that that comes right within a line of reasoning rather than a line of memory and consequently is not evidence, unless there is no objection to that. Did you say there is no objection to that, Mr. Haight?

Mr. Davis: May I try again?

The Court: Yes.

By Mr. Davis:

Q. 177. I do not want your reason why you now think anything, but if you can state any scientific fact which was known to you at the time which we may now infer of our own free will, as a matter of our inference, might have caused this blunder on your part, if it is a blunder, I would like that fact as a scientific fact?

A. It was a scientific fact known to me at that time, that in a vacuum tube, containing a certain amount of gas, the resistance of the tube to the passage of current between the electrodes was enormously increased in the dark space surrounding the cathode was made to extend out so as to embrace the anode. That is in terms of the language of that time. In other words, if the vacuum became so good that the mean free path was greater than the distance between the electrodes——

Q. 178. May I interrupt you. I wonder if we need a definition of that expression, mean free path.

The Court: I think you do.

A. The distance that a gas particle would have to go before it collided with another gas molecule.

Q. 179. Go back to the Crookes or Geissler tube. You start it and you see light in the tube?

A. Yes.

Q. 180. What is the dark space?

A. At a certain vacuum, a rather poor vacuum, you will observe in such a tube luminosity between the electrodes extending up to a narrow zone surrounding the cathode.

Q. 181. And in that narrow zone you have no luminosity?

A. Yes.

Q. 182. And that is the dark space?

A. Yes. As the vacuum of that tube is improved that dark space is seen to grow more and more extensive and as it does so the resistance of the tube to the flow of current increases. It increases very greatly when the dark space extends out to the point where it embraces the anode as well as the cathode and it would then be useful in a hot cathode tube to have the resistance of the tube to gaseous discharge as high as possible so as not to mask the pure electron discharge which one wishes to use with such a tube.

Q. 183. I hand you what I understand to be a copy of Defendant's Exhibit 31, being an article by Dr. Lilienfeld and Dr. Rosenthal or a paper of 1912, with a paper by Dr. Rosenthal, both being together as one exhibit.

The Court: I wonder if I may get some help before he goes into that answer. Is there any difference between an X-ray tube and a Fleming valve other than the potential on the plate or on the anode. I was wondering just where the field of the X-ray tube blends with the radio tube and a subordinate question is whether a radio tube is not an X-ray tube to the extent of the energy employed in the tube. I was wondering where they melt one into the other and whether you can help me on that.

Mr. Davis: I am always wondering myself when I am standing around these high-powered kenotrons.

The Court: It is only as it bears on this case and you can tell me or have the witness tell me.

Mr. Davis: The old-fashioned X-ray tube was not like the Fleming valve because it was a cold cathode. The Coolidge X-ray tube is not the same as the Fleming valve, because it has a high vacuum. The structure is the same, you have a hot cathode and a cold anode.

The Court: A highly evacuated Fleming valve.

Mr. Davis: Yes, sir. The difference between a highly evacuated Fleming valve—take the kenotron. It is the modern three-electrode tube without the third electrode. We are running into questions of terminology, but my understanding is that if the voltage is high enough to get up a velocity in the electron to cause it to emit X-rays when it strikes the anode, that that is an X-ray tube whether you call it so or not.

By Mr. Davis:

Q. 184. Is that right?

A. That is right.

Q. 185. If you ran a kenotrone at 100,000 volts, you would want to protect people around it against the X-rays that would come from it?

A. There is this thing to be said, Mr. Davis, that when the hot filament of the kenetron is functioning as cathode, you have a voltage drop of only perhaps a few hundred volts between cathode and anode, so that the electrons then from the main discharge in the kenotron have a velocity corresponding only to a couple of hundred volts. On the next half cycle, assuming that the kenotron is operating on alternating current, it is the cold electrode which is functioning as cathode and there are no electrons coming from it and therefore when the voltage is high across the tube there are no electrons flowing across the space.

Q. 186. But if you should run a kenotron in such a way as to consume 100,000 volts in a kenotron——

A. Then it becomes an X-ray tube. To complete my answer to your Honor's question, you do get X-rays when these two or three hundred volt electrons strike the cold plate or anode, but they are of such low penetrating power that they cannot get through the glass walls of the tube.

Q. 187. That is, in one case you are using Doctor —in the kenotron you are using it in series with the load and you are consuming the voltage in the load?

A. Yes.

Q. 188. And in the X-ray tube you consume the voltage where?

A. In the X-ray tube itself. The less voltage that you consume in the kenotron the more efficient the device becomes.

Q. 189. But the kenotron must hold back the whole voltage?

A. Yes, on the one-half wave, and let it pass through freely on the other half wave.

Q. 190. Referring to this Lilienfeld-Rosenthal article, are you familiar with the disclosures of those two articles taken as one?

A. I am.

Q. 191. If the tube therein disclosed were at any time in a condition of exhaust such that if a discharge flowed in it it would be a pure electron discharge, would that tube operate as an X-ray tube?

A. No, Mr. Davis, it could not.

Q. 192. Why could it not?

A. It could not because there would be no positive ions to bombard the main cathode and to there liberate electrons for the main discharge.

Q. 193. The main cathode being cold in that tube, is that right?

A. Yes.

Q. 194. How many ions does it take bombarding the cathode of that tube to create a given discharge or current or to make it possible, as compared with the number of ions to do the same thing in an ordinary old-fashioned X-ray?

A. It would take just as many.

Q. 195. Would this tube disclosed in this article operate at a vacuum somewhat higher than that of an ordinary old-fashioned X-ray tube or not?

A. I should say that it would.

Q. 196. And as you continued to increase the vacuum, what would happen?

A. The number of available positive ions would decrease and the positive ion bombardment of the main cathode would decrease and the current then, the main discharge current flowing through the tube, would decrease.

Q. 197. In that tube as shown and described there is a certain auxiliary anode which is described as an aluminum sheath. Do you remember that description?

A. Yes.

Q. 198. What is the structure there described and illustrated, the structure and arrangement of the auxiliary anode?

A. Shall I read, Mr. Davis?

Q. 199. Tell us what it is, if you remember.

A. It consists of a tube of aluminum as I remember it, which is at one end in very close proximity to the glass.

Q. 200. What do you say as an expert as to the possibility of cleaning up that anode shield so as to have it reasonably free of gas?

A. I would not know how to do it.

Mr. Davis: That is all of the direct.

The Court: I understand that you want to defer the cross-examination of Dr. Coolidge, or will you begin that this afternoon?

Mr. Darby: I understand we are prepared to start the cross-examination, but we would like to have an opportunity to go through the notebooks. We will make every effort to complete his cross-examination today.

Mr. Haight: I think Mr. Richmond can conduct the cross-examination of Mr. White right after lunch and that will give us a little more time with the notebooks.

(Recess was taken until 2.15 P. M.)

William D. Coolidge, resumes the stand.

Cross-Examination.

By Mr. Darby:

XQ. 201. The X-ray tube, Dr. Coolidge, is an electron discharge device, is it not? That is, suppose I confine it to the so-called Coolidge X-ray tube; that is an electron discharge device, is it not?

A. I would say so, yes.

XQ. 202. And in those X-ray tubes of yours, did you always employ pure tungsten electrodes as distinguished from filaments containing beneficial additions?

A. For the cathode, I think so.

XQ. 203. You still do today?

A. Yes.

XQ. 204. And when did the so-called Coolidge X-ray tubes first come on the market, commercially, if you know?

A. As I remember it, the first tube to leave the laboratory went out late in 1913. I do not remember, Mr. Darby, when the first tubes were put on the market.

XQ. 205. Well, was that tube that left the laboratory, did it leave for experimental purposes, or leave for actual use?

A. Left for actual use.

XQ. 206. And that was the latter part of 1913?

A. As I remember it, very late in 1913.

XQ. 207. Around November and December?

A. As I remember it, late in December.

XQ. 208. Late in December?

A. Yes.

XQ. 209. As I understand your testimony, Dr. Langmuir disclosed to you in December, 1912, the results of work that he had been carrying on in connection with electron emission; is that correct?

A. That is correct.

XQ. 210. And that was the first disclosure he made to you of the results of work he had been carrying on up to that time?

A. The question seems a little bit vague to me, because you see——

XQ. 211. Let me make it more definite. I find on page 325 of your notebook:

> "Dr. Langmuir tells me that in his study of Edison effect, the current in the case of a hot cathode is greater with a very fine vacuum of one or two-hundredths of a micron than it is at higher gas pressures (excepting the case of argon). This Edison current becomes measurable at about 1600 degrees C., and gets to a maximum value at about 2300 degrees C."

You there recorded what Dr. Langmuir had told you; that is correct, is it not?

A. That is correct.

XQ. 212. And you then state thereafter, or immediately following:

> "I will try this out at once in an X-ray tube in which I can heat the cathode to any desired temperature."

That idea of trying it out in an X-ray tube was your own original idea, was it not?

A. Dr. Langmuir suggested to me that I try this type of device in an X-ray tube on this date, December 10th.

XQ. 213. Dr. Langmuir suggested to you to try it out on an X-ray tube?

A. Yes.

XQ. 214. The notebook does not so state, does it?

A. No, sir.

XQ. 215. That is your independent recollection of the conversation had that day, is that correct?

A. May I have the question once more. (XQ. 215 repeated as recorded.) I am just a little bit confused as to whether you mean the note here or what I have already testified to.

XQ. 216. I mean that it is your independent recollection of the conversation had that day in the absence of any statement to that effect in the notebook, that Dr. Langmuir told you to try this out in an X-ray tube?

A. That he suggested to me to try it out in an X-ray tube—yes, sir.

XQ. 217. And then the note in your notebook continues:

> "The above would be in line with my observations on pages 171 to 175."

That is correct?

A. That is correct.

XQ. 218. And the entries on pages 171 to 175 relate to work that was done on May 8, 1912; is that correct?

A. May I just have those pages once more?

XQ. 219. Pages 171 to 175, the same ones that you mentioned?

A. The entries relate in part to work actually carried out on that date, and in part to experiments which I think of trying.

XQ. 220. But the entire entry was made on May 8, 1912?

A. Certainly.

XQ. 221. And on page 173 in this entry the following appears:

> "I believe that the above points the way to the ideal X-ray tube. It looks to me now as though, with the tungsten cathode, the degree of vacuum would play an entirely subordinate role,

provided, of course, it is high enough, and that there will no longer be any such thing as a too high vacuum. The tube resistance will apparently be determined by the temperature of the cathode."

That is a correct reading of the entry in your notebook?

A. Yes, that is.

XQ. 222. And it is to that matter that you referred, in part, at least, in your entry under date of December 10, 1912, where you stated:

> "The above would be in line with my observation of pages 171 to 175."

A. That is correct.

XQ. 223. That portion of the entry that I have just read to you that appears on page 175, is not that exactly the same thing, or is not that the same thing that Dr. Langmuir told you, or at least that you testified Dr. Langmuir told you on December 10, 1912?

A. I should say no.

XQ. 224. Why?

A. On December 10th, as I remember it, 1912, Dr. Langmuir told me of definite experiments that he had tried, and how he had succeeded in producing a reproducible pure electron discharge, and told me how he had done it, and suggested that I try such a pure electron discharge in an X-ray tube.

XQ. 225. And you had suggested exactly the same thing on May 8, 1912; is ~~not that~~ correct?

A. In a way, yes. But after that, I had tried the experiment to which I referred this morning, which was very discouraging indeed, and which made me feel at that time that one would not get from pure tungsten heated to a high temperature in a good vacuum an electron discharge.

XQ. 226. You are referring to the experiment where the current stopped while the cathode was still hot?

A. Yes.

XQ. 227. You knew that the cathode was maintained at a high temperature by ion bombardment, did you not?

A. Yes, but I did not understand it as well then as I do now.

XQ. 228. You knew that if the ions became scarcer, the heating would become less, did you not?

A. Yes, unless there was some other cause of heating.

XQ. 229. And you also knew that the ions would become less as the vacuum got better?

A. Yes.

MR. DAVIS: I do not like to interrupt the cross-examination, but if my brother's purpose is to prove that Dr. Coolidge would have reasoned so and so, if he would have been more intelligent than he was at the time, I think it would be immaterial.

THE COURT: I do not understand Mr. Darby's questions to be to that effect. I understand them to be somewhat different, and for that reason I am not sustaining the objection.

XQ. 230. You were running your pump at the time that observation was made by you, were you not?

A. Yes, Mr. Darby.

XQ. 231. Did it or did it not occur to you that the reason that the electron current ceased, was because there was no longer enough ions to keep the cathode hot?

A. Apparently not. If it had, I would not have been so much discouraged.

XQ. 232. It did not occur to you at that time?

A. Apparently not.

XQ. 233. And as I understand it it was because of the fact that it did not occur to you at that time that you were so much impressed by the result of the current stopping; is that correct?

A. I think that is correct.

XQ. 234. If you can tell me, do so, but I do not want any guess on it, just what reason for this effect did you think of at the time, that is, of the current suddenly stopping?

A. I cannot tell you at this minute just what my state of mind was at the time, except that I drew this discouraging conclusion that I did not get electrons from hot tungsten in a good vacuum.

XQ. 235. Did this convince you that electrons would not come out of the tungsten at dazzling white heat in a good vacuum?

A. That was the conclusion that I drew at the time, yes.

XQ. 236. And was this the first evidence that you had ever obtained yourself that indicated this?

A. I should say so, yes.

XQ. 237. And up to this time you thought electrons might come out of hot tungsten in a high vacuum?

A. Yes.

XQ. 238. But this experiment convinced you that your former opinion was wrong, as I understand it?

A. That is correct.

XQ. 239. And of course you know now that your conclusions were erroneous?

A. That is correct.

XQ. 240. When did you become convinced that your conclusions were erroneous?

A. I should say on December 10th when Dr. Langmuir told me of his experiments in detail. I believed his story, every word of it.

XQ. 241. You now know, do you not, that if you happened to have your cathode heated from an outside source to very high temperature, you know that the tube would have kept on operating as the vacuum got better and would have kept on operating at just the time that you found the discharge actually stopped?

A. That is correct.

XQ. 242. I understand that there would have been still enough gas to produce some ions under such a condition and that this hitting such a hypothetical hot cathode might have caused it to have a short life unless the filaments were quite large, but without considering that phase——

A. Excuse me, Mr. Darby, you confuse me a little bit by talking about filaments. I thought you were talking about this plate of tungsten that was used in that early tube.

XQ. 243. Did you not employ also a filament in that early tube?

A. No, sir.

XQ. 244. It was the plate of tungsten that you heated to incandescence?

A. Yes, sir.

XQ. 245. That is right. If at the time of that experiment you had had a filament in place of the hot tungsten plate, it is my understanding that there would have been still enough gas to produce some ions and that this hitting such a hypothetical filament maintained hot might have caused it to have a short life unless the filament was quite large, but I say without considering that phase of the matter, I want you to tell me whether or not in such a hypothetical tube the action would have been harmfully influenced by the small positive ionization that would have been present?

A. I do not think, Mr. Darby, that at that time the amount of ionization present would have been small. I had at that time a very massive tungsten target.

XQ. 246. Then, as I understand it, it is your belief that the amount of ionization present would have been harmful, is that it?

THE COURT: Won't you read that question again.

(XQ. 245 was repeated by the stenographer.)

A. (Continued.) I think, Mr. Darby, that the amount of positive ionization would have been very great because——

XQ. 247. Would it have been harmful?

A. Yes, Mr. Darby, harmful, if I may finish, harmful in this way, certainly, that the tube would have been very unstable indeed, that is, the filament would certainly have been heated by that positive ion bombardment in the vacuum which I would have had at that time in that tube and that would have made the tube very unstable as an X-ray tube.

XQ. 248. Now, in connection with your direct examination on the claims that were in your application as they were originally filed, have you any independent recollection today of the interpretation that you gave to those claims at the time you executed this application?

A. None whatever, Mr. Darby.

XQ. 249. Will you just very briefly tell me the difference in principles of operation of the so-called Coolidge X-ray tube and the old X-ray tube?

A. In the old X-ray tube the electrons were liberated from the cathode by positive ion bombardment. To get these positive ions it was then necessary to have an appreciable amount of gas in the tube. The presence of this gas and of these positive ions brought with them certain complicating circumstances——

MR. DARBY: Pardon me if I interrupt one minute. I find that we are getting more or less into repetition and unless there is any question in your Honor's mind as to the difference between them I think I can shorten the examination.

The Court: I think counsel or witnesses have made that reasonably clear to me before so that if you want to——

Mr. Darby: I can shorten it materially.

The Court: If you want to state it and ask if Dr. Coolidge agrees with you, very well. That may shorten it a lot.

XQ. 250. See if you will agree with me on this, that the difference in operation of the new Coolidge X-ray tubes is that it operates on the pure electron flow theory, whereas the old X-ray tubes operated on gas ionization theory, is that generally stated correct?

A. In a broad way, yes.

XQ. 251. And the operating characteristics, can you give me just a broad statement of the difference in operating characteristics in the same way?

A. I will not be able to make it quite as brief, but I will do the best I can. In the gas tube, the old X-ray tube, there were certain influences tending to increase the gas pressure in the tube as the tube was operated. There were some other influences at work which tended to diminish the gas pressure as the tube was operated. As a result of these various influences to which I have alluded, the tube was in general unstable. By adapting oneself to the condition of the particular tube at the time, he could get along with it, meaning by that that he could get a certain current to pass through it at a certain voltage for a certain length of time.

He had to adapt himself, however, as I have said to the state of the tube at the time. With the hot cathode high vacuum tube, such as we have here, the situation is entirely different. It becomes possible with this tube to get within limits any desired current at any desired voltage, and again within limits for any desired time. In other words, flexibility of the device is very much greater.

XQ. 252. Maybe I can expedite this answer, too, by stating I notice in your patent No. 1,203,495, that you outline eight characteristics of the gassy tubes. Before you begin the description of the new Coolidge X-ray tube—and may I sum it up in this broad statement, that the difference in the operating characteristics between the new tube and the old type X-ray tubes inherently flow from the utilization of the pure electron flow principle; is that correct?

A. I think that is correct, Mr. Darby.

XQ. 253. Now, as a matter of fact, as I understand your testimony, Dr. Langmuir pointed out to you this difference in principle between the new tube and the old tube; is that correct?

A. I do not remember Dr. Langmuir's telling me about the old tube, no.

XQ. 254. He pointed out to you the advantages to be obtained by using the new tube, the pure electron flow theory, did he not?

A. I do not think so, Mr. Darby.

XQ. 255. You do not?

A. Except in so far as he pointed out to me that by the pure electron discharge method, one could have reproducibility, perfect reproducibility of results. That is, up to that time we had had one method of getting the electrons out of the cathode, only one method, which was useful in X-ray work. Here was a new and very much better method revealed for the first time for getting electrons out of the cathode.

XQ. 256. Do you intend that last statement of yours as a modification of your answer to my question, or as an explanation of it, or is it just volunteered?

A. I should say it was in explanation.

XQ. 257. You do not intend it as a modification of your answer?

A. No, sir.

XQ. 258. Very well. Now, your patent recites after outlining all of these disadvantages, eight in number, the old X-ray tube:

> "In order to overcome these troubles met with in the X-ray tubes of the prior art, I remove the cause of the trouble, namely, the gas in the tube, and produce the electrons from the cathode necessary to the production of the X-rays, not by a bombardment of the cathode by positive ions due to ionization of the gas by the voltage impressed upon the tube, but by heating the cathode to incandescence by energy from a suitable source."

Dr. Langmuir told you that, did he not?

A. Yes. He suggested to me that I use a pure electron discharge in the X-ray tube as a source.

XQ. 259. Then your patent goes on:

> "In tubes made according to my invention I eliminate the action of positive ions as far as it is possible to do so by evacuating the tube to the highest vacuum which can possibly be attained and by thoroughly freeing the electrodes from gas."

Now, Dr. Langmuir told that to you; that was his idea, not yours?

A. He did not tell me how to make an X-ray tube embodying the pure electron discharge.

XQ. 260. Did he tell you to eliminate the action of positive ions as far as it was possible to do so by evacuating the tube to the highest vacuum which could possibly be obtained, and by thoroughly freeing the electrodes from gas; did he tell you that?

A. I do not remember whether he told me that or not.

XQ. 261. You knew?

A. I knew from my own knowledge.

XQ. 262. Do you deny that he did?

A. No. But I knew of my own knowledge about the harmful effect of positive ions in X-ray tubes of the prior art, but I think it unlikely that he told me that.

Mr. Darby: Read the previous question. (Previous part of the record repeated as recorded.)

XQ. 263. He did not tell you how to do it, but he told you to do it; is that correct?

A. He suggested that I do it, that is correct.

XQ. 264. And in doing it, he told you to eliminate the action of the positive ions, did he not?

A. Well, I do not remember his saying that to me, Mr. Darby.

XQ. 265. Did he tell you to "evacuate the tube to the highest vacuum which could possibly be obtained"?

A. I do not think so, Mr. Darby. I think Dr. Langmuir told me about his own experiments.

XQ. 266. That answers my question, Doctor. Did he tell you to thoroughly free the electrodes from gas?

A. I do not think so, Mr. Darby.

XQ. 267. Now, he told you that he had done all those things, did he not?

A. Not——

XQ. 268. In an electron discharge device?

A. But not in an X-ray tube.

Mr. Davis: The X-ray Coolidge patent is not in suit, and again I dislike in the slightest degree to interrupt cross-examination that has a value, but if it is directed to the validity of the Coolidge patent, I object. That is to save time. The patent is already in the record.

Mr. Darby: I am not trying the Coolidge patent here.

THE COURT: I think this cross-examination is within the field of reason, Mr. Davis.

By MR. DARBY:

XQ. 269. You say you told me just a minute ago, Dr. Coolidge, that an X-ray tube is an electron discharge device; that is correct, is it not?

A. That is correct.

XQ. 270. Then your patent states:

> "as a cathode I ordinarily use a tungsten filament."

Dr. Langmuir told you to use a tungsten filament, did he not?

A. It is only the form of that question that troubles me at all, Mr. Darby; I do not know that Dr. Langmuir said to "Coolidge, use a tungsten filament in this X-ray tube," but he did tell me about his experiments in which he had used tungsten filaments.

XQ. 271. Did Dr. Langmuir suggest to you that you use a tungsten filament?

A. I do not remember, Mr. Darby.

XQ. 272. Do you deny that he did?

A. No, sir.

XQ. 273. You do remember that the idea of using a tungsten filament was not your original idea, don't you?

A. You have called attention already to one case in which I did have the idea of using a tungsten filament as a source of electrons in an X-ray tube.

XQ. 274. I see. Then that was your original idea that you carried right with you up to this day of December 10, 1912; I understood from that you had abandoned the idea?

A. I did abandon the idea.

THE COURT: I did not get that.

(Answer repeated by the stenographer as follows:

"A. I did abandon the idea.")

XQ. 275. And the ultimate result of the present tube employing a tungsten filament was Dr. Langmuir's suggestion to you of December 10, 1912?

A. It was the result of Dr. Langmuir's communications to me of December 10th.

XQ. 276. And that communication explicitly contained a suggestion to use a tungsten filament, did it not?

A. I think so.

XQ. 277. All right. Then your patent states:

> "I have found that electrons will be emitted from such a cathode."

Tungsten filament cathode——

> "which electrons will traverse the space between the cathode and the target under the influence of the electromotive force impressed upon the tube, and by bombardment of the target, will give rise to X-rays."

That was part of what Dr. Langmuir suggested to you, was it not?

A. Well, Dr. Langmuir certainly did not——

XQ. 278. Can you answer that?

Mr. Davis: Let him answer it.

XQ. 279. Will you answer the question, please, and explain it later?

A. Well, I guess the answer is yes and no. If I may explain, I should say that the experiment which Dr. Langmuir described to me, the work which he told me about, was a small tube with two metal filaments, tungsten filaments in it. It certainly was not an X-ray tube, and I did not feel then, and do not feel now that Dr. Langmuir told me how to make an X-ray tube. He suggested to me that I make an X-ray tube employing the pure electron discharge. I had a great deal to learn, Mr. Darby, in doing that work. I have told you about that point.

XQ. 280. You have said several times, Doctor, and I am confining my entire cross-examination to expressed suggestions to you on express things. Now, I understand fundamentally that you say that Dr. Langmuir suggested that you construct an X-ray tube, having a hot filament of tungsten, employing pure electron flow; is that correct?

A. That is correct.

XQ. 281. Dr. Langmuir suggested that to you?

A. That is correct.

XQ. 282. And I also am assuming in my questions, that Dr. Langmuir knew what an X-ray tube was, or that he would not?

A. I am sure he did.

XQ. 283. That he would have to have another electrode to which the electrons would have to travel?

A. Certainly.

XQ. 284. Then we are not at disagreement?

A. No, sir.

XQ. 285. Now, my question is, did Dr. Langmuir suggest to you any such arrangement that

> "electrons will be emitted from such a cathode, which electrons will traverse the space between the cathode and the target under the influence of the electromotive force impressed upon the tube, and by bombardment of the target, will give rise to X-rays."

A. I do not think so, Mr. Darby.

XQ. 286. You do not think he suggested that to you at all?

A. I think that Dr. Langmuir was sure that I knew that.

XQ. 287. I see. Was he sure that you knew that electrons would be emitted from the tungsten cathode?

A. I do not know, Mr. Darby, just how sure he was of the effect of his communication to me, but he might very safely have assumed that, because I had the greatest faith in what Dr. Langmuir told me about his work.

XQ. 288. The next statement of the patent is:

> "In this new type of tube positive ions appear to play no role whatsoever."

Dr. Langmuir told you that, did he not, that in a tube constructed in accordance with his suggestions, that positive ions would play no part whatever in the operation of the tube?

A. I do not say that, Mr. Darby.

XQ. 289. You do not think so?

A. I do not believe Dr. Langmuir could have known what the effect would be of using, let us say, one-hundred thousand volts on that tube.

XQ. 290. You do not think he told you that?

A. I do not think so.

XQ. 291. Then the next statement in your patent is:

> "Gas pressure in the tube being thus eliminated to the highest possible degree, those features of instability in the tubes of the prior art which it can now be seen were due to the presence of the gas in the tube are likewise eliminated."

Did not Dr. Langmuir tell you that with a pure electron-flow in the X-ray tube, that the "features of instability of the tubes of the prior art would be eliminated"?

A. I do not remember, Mr. Darby.

XQ. 292. Do you deny that he did?

A. No, sir.

XQ. 293. Then you state:

> "In the preparation of the tube the glass is first freed from moisture and gas by heating and other approved methods and the electrodes preferably are freed from gas as by heating them to a high temperature in a vacuum."

Dr. Langmuir told you that in connection with the work that he had been doing, did he not?

A. He told me that he had used such methods in his exhaust work.

XQ. 294. Then the patent continues:

> "Exhaustion of the tube is preferably carried on by means of a pump which will remove vapors as well as gases."

And he did tell you that in connection with his prior work, did he not?

A. I do not think that Dr. Langmuir had had such a pump at that time.

XQ. 295. He told you that in his exhaust that he removed vapors, as well as gases, did he not?

A. Yes, sir.

XQ. 296. And he suggested that is what you should do in obtaining gas from the X-ray tube?

A. The form of those questions is very troublesome to me, Mr. Darby, because the answer always seems to be the same, that Dr. Langmuir told me about his own experiments, and then suggested that I try the pure electron discharge in an X-ray tube. I do not think he went into details as to how that X-ray tube could be made embodying that pure electron discharge.

XQ. 297. He went into details of telling how to get a pure electron discharge, that is, with regard to the degree of evacuation and how to get the evacuation?

A. He told me how it was obtained.

XQ. 298. That is exactly what I mean.

A. There is quite a difference, because in one case we are dealing with little tungsten filaments and in another case we are dealing with large tungsten masses which Dr. Langmuir did not have to deal with and which I had to learn how to deal with.

XQ. 299. In other words, Dr. Langmuir told you how he had freed what he was handling of gas and water vapor in order to get the high vacuum?

A. Yes, sir.

XQ. 300. And he suggested to you to obtain a high vacuum in an X-ray tube to produce a new X-ray tube operating on a new principle, on pure electron flow?

A. That is right.

XQ. 301. His principle of pure electron flow?

A. That is right.

XQ. 302. The next statement of your patent is:

> "The electrodes should be made of refractory metal such as tungsten so that they will withstand the very high temperatures attainable by operating the tube while connected to the pump, whereby gas may be effectively driven out."

Dr. Langmuir had told you that you had to drive the gas out of the tungsten filament, did he not, in your X-ray tube?

A. He told me that he had driven the gas out of tungsten filament.

XQ. 303. He suggested to you that you should do the same thing, did he not?

A. I do not know how to take that question. He suggested that I use pure electron discharge in an X-ray tube.

XQ. 304. Did he specifically suggest to you that you use tungsten filament from which you should or somebody else should expel all of the gas?

A. I do not think so, Mr. Darby.

XQ. 305. Did he suggest to you the use of tungsten filament—did he not?

A. I think so.

XQ. 306. So as I understand your last answer, he did not suggest to you that the tungsten filament had to be gas freed?

A. Certainly by implication.

XQ. 307. But not in so many words?

A. Insofar as I can remember.

XQ. 308. Then it was only by implication that you stated what Dr. Langmuir told you in answer to Q. 103 in your direct examination in the following language, and in answer to the question: "What did Dr. Langmuir tell you at that interview?

A. That when filaments had been carefully freed from gas in a high vacuum he had found it possible to maintain a discharge" and so forth. You did not intend that answer to imply that Dr. Langmuir had suggested to you to use that in X-ray work, did you?

A. I am getting a little bit confused by your language, Mr. Darby, but it seems to me that I stated over and over again what did take place, and Dr. Langmuir told me about his experiments and told me how he got tungsten filaments free from gas and operated them in a very high vacuum and got pure electron discharge which was reproducible and suggested that I use such a discharge in an X-ray tube.

Mr. Darby: I move to strike out the answer as not responsive.

Mr. Davis: May I have the last question read.

(The stenographer repeated the last question.)

Mr. Davis: I have not this part of the record, and I do not know how my brother got it, but the question is "What did Dr. Langmuir tell you at that interview? A. That when these filaments had been carefully freed from gas he had found it possible,'' and so on, nothing about his telling Dr. Coolidge to do anything, exactly what the witness has been saying right along. He is saying exactly what he said before in almost the same language. I move to strike out the question.

Mr. Haight: May we have the question read.

(The question was repeated by the stenographer.)

Mr. Haight: We think it is argument and we consent to striking it out.

The Court: In the absence of agreement I shall grant both motions. The answer and the question both go out.

Mr. Darby: That is entirely agreeable to me.

By Mr. Darby:

XQ. 309. Now, your patent states: ''My novel apparatus, therefore, has the following valuable and striking characteristics. First, the resistance of the tube, and, hence the penetrating power of the Roentgen rays produced in the tube, may be controlled with certainty, and may be instantly increased or decreased at will, by raising or lowering of the temperature of the cathode.'' Did Dr. Langmuir suggest to you or tell you that that would inevitably follow from employing his pure electron discharge?

A. I do not remember, Mr. Darby, but I doubt it.

XQ. 310. Then the second point follows: ''Second, a much more homogeneous bundle of X-rays can be produced even though a several-fold increase, or decrease of gas pressure takes place in the tube, providing the pressure remains within the limits above indicated.'' Had Dr. Langmuir told you that the operation would be independent of the degree of vacuum below a certain minimum value?

A. To this extent, Mr. Darby, he had told me that in his own experience the electron emission was independent of the vacuum beyond a certain point of evacuation.

XQ. 311. Then am I to understand that he did not tell you specifically that the X-ray tube that you would construct would not depend upon the degree of vacuum?

A. I think that is correct, Mr. Darby.

XQ. 312. And then the patent continues: "Third, as the discharge can pass through the tube only when the heated electrode is made the cathode, the tube may be operated on alternating current almost equally as well as on direct current."

Did Dr. Langmuir tell you that in the X-ray tube that you would construct that that would be the case?

A. I doubt very much his having hazarded such a statement as that. Dr. Langmuir's work as I have told you was done with relatively low voltages, a couple of hundred volts as I remember it——

Mr. Darby: I move to strike it out.

The Court: Beginning with "Dr. Langmuir's work as I have told you," goes out.

XQ. 313. The next is "Fourth, if desired, a tube may be proportioned to give over a predetermined range of impressed voltage X-rays of substantially uniform penetration."

Now, did Dr. Langmuir tell you that in the X-ray tube which would result from his suggestion if followed by you that the voltage would be determined by the voltage delivered by the transformer that you used to obtain the potential for the anode?

A. I doubt his having made that specific statement.

The Court: I interrupt now only because Mr. Davis made a former objection. So far as you have been cross-examining as to the disclosure made by Dr. Langmuir to Dr. Coolidge in December of 1912——

Mr. Darby: And I still am.

The Court: —for the purposes of this case, of course,——

Mr. Darby: Yes, sir.

The Court: But with the last question I begin to wonder whether you were not going beyond that field.

Mr. Darby: No, sir. I am sticking strictly to the testimony already in the case.

The Court: My difficulty is this: I can see how that question would be very pertinent to the patent for the X-ray tube, but I miss its relation to the case at bar, and I raise the question simply because Mr. Davis had earlier objected and I thought it was a continuing objection.

Mr. Darby: The validity or invalidity of the Coolidge patent is something that I am not the least bit concerned with.

The Court: Of course, it has nothing to do with this case, but I thought the last question was possibly near if not over the border line in pertinence to the Langmuir disclosure.

Mr. Davis: Perhaps Mr. Darby will be willing to state what the connection is.

Mr. Darby: I would not like to do so to the witness.

The Court: I am not going to ask you to do that.

Mr. Darby: I will be glad to show your Honor.

The Court: You may proceed. I wanted you to understand that my prior ruling was based on the fact that I thought the objection was not valid then, but I was beginning to think that the point would be arrived at where it might be valid.

By **Mr. Darby:**

XQ. 314. The patent then says:

"One of the main causes for the uniformity of the penetrability of the X-rays is to be ascribed

> to the fact that the operation of the tube is not dependent upon positive ion bombardment of the cathode."

I think you stated once before that Dr. Langmuir told you that in an X-ray tube constructed embodying what he disclosed to you, that the operation would not be dependent upon positive ion bombardment; that is correct?

A. I do not remember having made such a statement.

XQ. 315. Is it correct then? Did Dr. Langmuir tell you that an X-ray tube constructed in accordance with his suggestion to you, that the operation would not be dependent upon positive ion bombardment of the cathode?

A. I do not remember whether he said that or not, Mr. Darby.

XQ. 316. My difficulty, Dr. Coolidge, is that you do not remember whether he said it or not. Would you deny that he did say so?

A. No.

XQ. 317. Then the patent continues:

> "Another cause is its complete independence of vacuum changes within the permissible range of pressure."

Did Dr. Langmuir tell you that the X-ray tube constructed in accordance with his suggestion to you would operate independently of vacuum changes within the permissible ranges of pressure below a certain minimum?

A. I do not remember his having made any such statement to me, Mr. Darby.

XQ. 318. And the next statement of the patent is:

> "It will also be noted that with the high vacuum existing in the tube, the mean free path be-

tween gas molecules is much greater than the distance between anode and cathode, and, therefore, very few electrons can collide with gas molecules in passing from cathode to anode, practically all of the electrons reach the target with uniform velocity."

Did Dr. Langmuir suggest to you in the X-ray tubes that you were to construct that you should place the cathode close to the anode?

A. I do not remember, Mr. Darby.

XQ. 319. And the patent continues:

"Because of the low gas pressure the number of positive ions is so small that the filament is not heated at all by bombardment."

Did Dr. Langmuir tell you in the X-ray tube that you would construct that the filament would not be heated by bombardment?

A. I do not think so.

XQ. 320. You do not think so?

A. No.

XQ. 321. The patent states:

"The wall of the tube exposed to the anode is not heated by secondary cathode rays from the anode, thereby removing the limitation formerly imposed by local tube heating."

Did Dr. Langmuir tell you that that would be the fact with respect to the X-ray tube that you might construct in accordance with his suggestion?

A. I doubt it.

XQ. 322. You doubt it?

A. Yes.

XQ. 323. Then, follow me closely on this, Doctor, please. As I understand it, to sum this up very briefly, Dr. Langmuir suggested to you that if you would build an X-ray tube, that is, an electron discharge device, designed for the purpose of producing X-rays with the usual electrodes, that is, with the usual target, or a target—put it that way—and an incandescent cathode made of tungsten in a vacuum, the vacuum being attentuated so as to practically eliminate the production of positive ions, and heat your incandescent cathode independently of the voltage applied between the two electrodes, that you would get a good X-ray tube?

A. I do not think he used just that language, Mr. Darby, but I think that that is what the suggestion amounted to.

XQ. 324. In the operation of the Coolidge X-ray tube, space charge is not a factor, is it?

A. It is not a factor limiting the discharge current.

XQ. 325. That is what I mean.

A. That is right.

XQ. 326. And the voltage that you employed is far higher than what is necessary to draw all of the electrons emitted from the hot cathode to the anode?

A. That is not exactly right, Mr. Darby.

XQ. 327. Straighten it out for me, will you please?

A. With the focusing device there, the voltage used on the tube does not draw to the anode all of the electrons that are emitted by the filament. Some of them fall back again into the cathode.

XQ. 328. True, but if the focusing device was eliminated my question would be correct?

A. Yes.

XQ. 329. That is, the voltage is far higher than what would be sufficient to draw all of the electrons emitted from the cathode over to the anode?

A. Yes, sir.

XQ. 330. The current is determined by the cathode temperature at the operating voltages; that is correct, is it not?

A. That is correct.

XQ. 331. In all of these respects the case is just the opposite to that of a three-electrode audion, for example, in which space charge is a factor, the voltage is not high enough to draw to the anode all of the electrons emitted by the cathode, and the current is determined by the voltage and not by the cathode temperature; that is correct, is it not?

A. There is that difference, yes.

XQ. 332. It was of course part of Dr. Langmuir's suggestion to you that in the tube to be constructed embodying his idea of pure electron flow, by reason of the existence of a high vacuum, or the absence of pressure, it was part of his idea that he suggested to you that the vacuum had to be maintained, was it not?

A. I think so, Mr. Darby.

Mr. Haight: Possibly I could save time by asking the witness two or three questions instead of suggesting them to Mr. Darby.

The Court: Any objection?

Mr. Davis: No objection.

Cross-examination (Continued).

By Mr. Haight:

XQ. 333. Did Dr. Langmuir suggest to you that the hot wire cathode be placed close to the anode so that the charges on the glass would have little effect?

A. I do not remember his having made such a suggestion as that.

XQ. 334. Did he suggest that the focusing of the rays might be accomplished by deflecting them magnetically, while close to the anode and while moving with low velocity, and that they would then acquire velocity in moving towards the anode?

A. I do not remember, Judge Haight. I might say that I was familiar with the method of magnetic focusing, otherwise I might remember that better, but

I had done a lot of work with that method myself in times past.

XQ. 335. Let me ask you this question. Possibly you have answered it a number of times in the course of your cross-examination. As I understand it, the improved X-ray tube, of which it is said that you are the inventor, and which is covered by a patent that has been referred to, the improvement was that you used instead of a gas tube a high vacuum tube. Is that in general the improvement that was made, the change that was made over the prior tube?

Mr. Davis: It seems to me that this is entirely outside of any question raised in this case.

Mr. Haight: I will lead right up.

The Court: Will you not read the question?

Mr. Haight: I will strike it out.

XQ. 336. I understand that the X-ray tubes of the prior art before you made some changes worked on the principle of gas; that is right?

A. That is right.

XQ. 337. You changed that principle completely and worked on the principle of a high vacuum?

A. Yes.

XQ. 338. And the idea that the pure electron discharge in a high vacuum should be used in an X-ray tube was suggested to you by Dr. Langmuir?

A. That is correct.

XQ. 339. So that the backbone of your invention was Langmuir's suggestion?

Mr. Davis: That I object to. The last thing the witness can do is to qualify in that way.

Mr. Haight: I should think that the witness would know what the backbone—if I may use that crude but rather expressive expression—is.

The Court: Do you press your question?

Mr. Haight: Yes, sir.

The Court: Then I will hear you.

Mr. Haight: I have already stated my reason.

The Court: You do not care to be heard further?

Mr. Haight: No, sir.

The Court: Then I sustain the objection.

By Mr. Haight:

XQ. 340. I am wondering this, whether what you wrote in your notebook on December 10, 1912, namely, "I will try this out at once in an X-ray tube in which I can heat the cathode to any desired temperature," is not a more accurate statement as to how you came to apply the principle which Dr. Langmuir had advised you of on that day to an X-ray tube than your present recollection that Dr. Langmuir suggested to you that you so apply it?

A. I do not think so, Judge Haight.

XQ. 341. You had already in the preceding May yourself sensed exactly the same principle, hadn't you?

A. Sensed it perhaps, but failed with it.

XQ. 342. Failed with it in practice. I understand that. But you said on May 8th that you believed that the ideal X-ray tube would be a high vacuum tube, didn't you?

A. Yes, sir.

XQ. 343. And then you had conceived this kind of an X-ray tube, I mean the kind that you eventually did produce?

A. I certainly thought of it. I do not know about that word "conception of an idea" as applied here.

XQ. 344. You said, "I believe that the above points the way to the ideal X-ray tube." That is true, is it not?

A. Yes, that was my opinion.

XQ. 345. And that was the result of your own experiments and observations?

A. Yes, sir.

XQ. 346. Now then came December 10th, and Dr. Langmuir and you working in the same laboratory, he knew you were working on X-ray tubes, I suppose?

A. Yes, sir.

XQ. 347. And you knew that he was working with some of the phenomena in vacuum tubes?

A. Yes, sir.

XQ. 348. And he then told you of what he had found in respect to the electron discharge in a high vacuum, is that right?

A. Yes, sir.

XQ. 349. Then you wrote down in your notebook that day: "I will try this out at once in an X-ray tube," didn't you?

A. Yes, sir.

XQ. 350. Don't you think that in view of what you had conceived in May but which you had not been able to work out definitely, and in view of the fact that he had told you what he had accomplished in electron discharge, and in view of the statement contained in your notebook, which I have just read to you, don't you think that the idea of applying that principle to an X-ray tube was your own rather than one suggested by Dr. Langmuir?

Mr. Davis: Just a moment.

Mr. Haight: It is the same question over again.

Mr. Davis: That is one of the disadvantages of having two counsel cross-examining the witness.

Mr. Haight: It is the same question I asked.

(Discussion.)

Mr. Davis: In this case, I have no objection whatever to that question, if it is merely as to who it was in this interview between these two scientists that really made the suggestion, that is all.

Mr. Haight: That is all I am trying to find out.

Mr. Davis: I have no objection to that.

The Witness: It was Dr. Langmuir's, Judge Haight.

By Mr. Haight:

XQ. 351. Then, the opinion I have referred to, having induced you to change your mind, as expressed when Mr. Darby cross-examined you a while ago——

A. No, Judge Haight, there is this thing I would like to correct. You say that I have had an idea once upon a time of using a hot filament, hot cathode, in an X-ray tube, but that I had not fully worked it out. Now, as a matter of fact——

XQ. 352. That is what you said, Doctor; I did not. You said you had not worked it out?

A. I thought that I made it stronger than that; I meant to. My feeling was then that I had failed flatly——

XQ. 353. All right.

A. —and stopped.

XQ. 354. Now then, Dr. Langmuir came along, and told you that working with hot cathode filaments, he had been able to get a pure electron discharge in a high vacuum; is that right?

A. That is right.

XQ. 355. Now then, did not that immediately awaken in your mind:—Why, here the reason why I failed on this same thought before, was because I was working on a large piece of tungsten. Now, if I can just take this piece of filament and put it in an X-ray tube, I can get what I have been looking for for so long?

A. That idea certainly came to my head, but I am very positive——

XQ. 356. Did not that originate with you rather than with Dr. Langmuir?

Mr. Davis: Let him finish his answer.

A. I am very positive that Dr. Langmuir made the definite suggestion to me at that time immediately after telling me about his own experiments, and before I had had time to think the thing over in its bearings on the X-ray tube problem, in which I was so much interested.

XQ. 357. And do you suggest why you did not write that down in your notebook?

A. Well, I am rather surprised that I did as well as I did, Judge Haight. I did not keep notes very consistently, and they usually are briefer than they ought to be.

XQ. 358. They seem to be fairly full there, along this time, they run along every day, don't they (handing book)?

A. I hope so. I am afraid not every day.

XQ. 359. Look before you get up. I say every day. I mean practically every day.

A. I think it depends on what part of that notebook you strike.

XQ. 360. I am referring to this particular part right along here, where the going is good.

A. Here, I see a certain attempt—18/19/20.

XQ. 361. And before that the 5th?

A. You will find them oftener after this, Judge Haight, because we soon became very much interested indeed in that type of X-ray tube.

XQ. 362. You have no other suggestion to make as to why you did not write down in your notebook that Dr. Langmuir suggested to you the application of this principle to X-ray tubes, than the fact that you sometimes did not keep full notes?

A. No, sir.

MR. DARBY: That is all.

MR. DAVIS: That is all.

(Witness excused.)

MR. RICHMOND: Your Honor, at the close of the cross-examination of the witness Kelly, requests were made for some data, and I now wish to have marked for identification "Kelly Data for Defendant's Exhibit No. 56," E for Identification. This data we submitted to our opponents the day before yesterday.

(Received and marked "Defendant's Exhibit N for Identification.")

JOHN V. L. HOGAN.

JOHN V. L. HOGAN, was recalled in rebuttal, on behalf of the plaintiffs, and having been previously duly sworn, testified further as follows:

DIRECT EXAMINATION.

By MR. EDMONDS:

Q. 194. Mr. Hogan, I take it that you are familiar with the defense's material in this case, including the prior patents and publication as referred to by Professor Chaffee, and the prior knowledge and use and the deposition as taken in San Francisco?

A. That is correct.

Q. 195. Will you say if you find in any of this material the disclosure of a cathode for electron discharge apparatus consisting largely of a highly refractory metal and a surface layer of material having an electron emissivity at a given temperature materially greater for unit surface than said refractory metal independently of and in the presence of positive ionization?

A. I do not.

Q. 196. Do you find in that material a device operating by pure electron discharge independent of positive ionization having a conductor comprising a refractory metal and a surface film of thorium metal vaporizable at a temperature above about 2300 degrees K., and having a greater electron emission when at incandescence, in a non-striking vacuum than said refractory metal?

A. No, I do not.

Q. 197. Do you find there an electrical discharge device, having an electrode comprising in part at least oxidizable thorium material, said electrode having at a temperature of about 1300 to 1380 degrees absolute an electron emission substantially equal to that of tungsten at about 2000 degrees absolute?

A. No, I do not.

Q. 198. And finally, an electrical discharge device having an electrode comprising metallic tungsten and thoria, said electrode being subjected to a temperature of about 2200 to 2350 degrees K., and having an electron emission a thousand times as great per unit of surface as tungsten in a vacuum too high to permit of positive ionization?

A. No.

Q. 199. Do you find in that material considered apart from any reference to the Wehnelt cathode any means for increasing the electron emissivity of the cathode other than increasing its temperature?

A. No.

Q. 200. Will you assume that someone put a thoriated tungsten lamp filament in a vacuum tube in 1911 or 1912, and that the vacuum was the ordinary X-ray vacuum? Would the film of thorium be formed under those conditions?

A. No. Even with proper temperature treatment, the film would not form because thorium is so sensitive to oxidation that the partial pressure of oxygen in even the best X-ray vacuum of the old days would be enough to destroy (by oxidation) the thorium as fast as it appeared.

Q. 201. I think you might explain that a little more fully at this point if you will.

A. I have made an additional assumption and that is to say that in addition to putting in a lamp filament one gave it a temperature treatment corresponding to activation treatment that is described in the second patent, and I have said that even though that were done so that thorium would distill outward through the filament to the surface, as it appeared on the surface of the filament the oxygen which would necessarily be in the tube at a pressure of three microns or more, that is to say an X-ray tube pressure, it would instantaneously, practically instantaneously oxidize and destroy the thorium on the surface of the filament and so prevent its contributing to emission.

Q. 202. So that what emission you got from such a tube would be tungsten emission and not thorium emission?

A. It would be practically the emission of pure tungsten, and, of course, if you do not give it the temperature treatment the thorium would not even come out of the filament so that then the emission would be simply that of pure tungsten.

Q. 203. Now, will you assume a very high vacuum, the highest possible vacuum, were given a tube and the tube was operated at the normal filament temperature for tungsten cathodes, would the film be formed under those conditions?

A. I will have to define highest possible vacuum in that connection and for the assumption of your question I will take that as being not merely a very high vacuum such as would be required for space charge operation in accordance with the first patent in suit, but also the character of vacuum, the quality of vacuum, which has a partial pressure of oxygen far below that which is necessary for the 3/2 power operation and sufficiently low to prevent rapid or in fact any oxidation of substantial amount of thorium.

If the vacuum were as good as that, that is to say, as good in the vacuum in the modern tubes using all four of the patents in suit, and the filament were operated at normal cathode temperatures for tungsten, that is to say temperatures above 2400 degrees K., the bright white temperature so to speak of the ordinary tungsten lamp, (which were exceeded if anything in the tungsten filament vacuum tubes used in 1913, or thereabouts, 1912, perhaps) then the thorium if there was thorium in the filament would diffuse to the surface of the filament but would immediately evaporate from the filament. The rate of evaporation is so high at those temperatures that it would not remain as an active monatomic layer on the surface of the tungsten. Consequently at those temperatures first whatever thorium might be in the filament would rapidly be exhausted and secondly, the emission would be little if any higher, probably no higher than that of pure tungsten. Certainly after the exhaust it would be no higher and even during the evaporation I doubt if it would be substantially higher.

Q. 204. So that under the conditions stated you would be getting no useful result whatever from the thorium?

A. That is correct.

Q. 205. Do you find in the defense material any disclosure of an electrical discharge device comprising electrodes, one of which contains thorium, an inclosing envelop the space within which is evacuated to a pressure so low that positive ionization is substantially absent, and a quantity of a vaporizable reagent capable of preventing the oxidation of thorium in communication with the space within said envelop?

A. No, I do not.

Q. 206. Or a disclosure of an electrical discharge device comprising electrodes, one of which consists of metallic tungsten and a thorium material in an oxidizable state, an inclosing envelop, and a quantity of a vaporizable reagent within said envelop capable of preventing the oxidation of thorium at an elevated temperature?

A. No, that combination does not appear.

Q. 207. Or an electrical discharge device comprising a sealed envelop, electrodes therein one of which is of the thoriated type and a film of magnesium deposited on the inner surface of said envelop?

A. No.

Q. 208. Or an electrical discharge device comprising a container, electrodes therein one of which consists largely of refractory metal and contains an oxide of a metal of high electron emissivity which when rendered active is sensitive to ion bombardment together with a reducing agent, and a quantity of alkaline earth metal, the latter being deposited as a film on the inner wall of said container?

Mr. Darby: I do not know how far——

Mr. Edmonds: I am through.

A. No, I do not find that either.

Mr. Darby: I think those were all questions for the Court to be answered.

Q. 209. In his answer to Q. 34, Professor Chaffee referred to the following prior patents and publications, the patents of Malignani, Dwyer, Von Recklinghausen, Merritt, Soddy, Clark, Clough, Marshall and MacKay, and the publications of Soddy, Doane, Hupka, Kunz and Kemp and Whitney. You are familiar with those, are you not?

A. Yes, I have read all of them.

Q. 210. I wish you would take up those patents in the order in which Professor Chaffee discussed them, if you find that convenient, and say what if anything you find in them bearing upon the second, third and fourth patents in this suit?

A. If it is equally satisfactory I think it might be more convenient to take these up in the order of the exhibit numbers, that is to say in the order in which they were introduced. I think that agrees in general with the order that Dr. Chaffee used, but it makes it more or less chronological.

The first patent is that issued to Malignani, No. 537,693, April 16, 1895. This is a lamp evacuating patent and has to do with the so-called chemical evacuation of lamps. Malignani in the process described first evacuates the lamp to about two millimeters gas pressure, page 1, line 36 of the patent. That corresponds to 2000 microns pressure.

He then lights the filament, driving off, or as he calls it generating, gases in the filament, the reference being page 1, line 40, and then he vaporizes arsenic, what he calls "sulphuric," or iodine, which as vapors are intended to combine with gas within the lamp and to precipitate.

The Malignani process as it is referred to in the lamp industry used phosphorus instead of arsenic or iodine or "sulphuric," which I believe means sulphur, and in any event the whole exhaustion effected depends upon ionization of the vapors or gases and is not a simple absorption; that is to say, in the lamp process when the phosphorus was vaporized in the lamp with the filament lighted, the lamp would glow as a result of the ionization of the gases under the potential applied across the filament terminals and in that period of glow or of extremely intense ionization the improvement of the vacuum would take place.

The process was not used so far as I have been able to learn on low voltage lamps, for the simple reason that without high voltage across the filament terminals, the necessary ionization would not take place.

Of course, the disclosure and the practical use of the process involved lamps, not thermionic tubes, not tubes containing any metals or electrodes other than the filament. Of course, there was no highly oxidizable thorium filament.

The initial pressure was very high and while it was reduced by the vaporizing and ionization clean-up to a fair lamp vacuum as of that time, even the final pressure was too high to be tolerated in a good electronic device.

As to any indication of the amount of reagent, if one may call the phosphorus a reagent for the clean-up, it is perfectly clear and it is stated in a number of patents which I may call Malignani improvement patents, that the amount of phosphorus to be used must be minimized. The reason for that is also simple. The reason is that the device is a lamp and the walls must not be clouded if it is to be a satisfactory commercial article.

As to the specific materials suggested by Malignani, it has been found impossible to activate a thoriated filament by temperature treatment in the presence of vapors of arsenic, sulphur, or phosphorus. As to iodine, while I know of no tests having been made of it, is clearly of such a high vapor pressure as to be of no utility in a thermionic device.

We all remember bottles of iodine in the chemical laboratories in which the blue vapor even at room temperature is perfectly visible, and that of course means a very high pressure in terms of lamp pressures.

Certainly, there is no suggestion in the Malignani patent of any keeping action as a result of any of the materials used. The clean-up is a simple lamp clean-up going from a very high pressure of thousands of microns to a lamp pressure of the order of ten microns or less, not below one or two microns in any event, and once that is done the reagent is through, its function has been performed and there is no suggestion that it has any further utility.

One other point might be mentioned in connection with this Malignani patent, and that is, that in the customary use of mercury pumps with lamps, the phosphorus that was used in the Malignani process, that is, phosphorus in general, and I am not referring to any particular kind of phosphorus, but phosphorus as used in the Malignani process, does not take up the mercury vapor so far as I have been able to find, and consequently the partial pressure of mercury amounting to a micron and a half at room temperature would remain within any tube in which one used a mercury pump without special means of removing mercury vapor.

I think that covers the Malignani patent and I will take up next Defendant's Exhibit 7, which is U. S. Patent 596,694, issued to Dwyer on January 4, 1898.

This again is a lamp evacuating patent and in the process described Dwyer pumps his lamp, as for example by a mechanical or mercury pump, page 1, line 21, to what was probably a lamp vacuum of a few microns. He then lights his filament to expand the gases and to drive off gas particularly from the joints as illustrated in Figs. 2 and 3 of the patent, the joints where the filament is fastened to the lead-in wires.

Q. 211. May I interrupt, Mr. Hogan? This vacuum that you have referred to in connection with this patent corresponds to what he speaks of as a partial or incomplete vacuum at line 26 of the first page of the specification?

A. Yes. He says that that is readily obtained by a good mechanical or mercurial pump, and in saying two or three microns, I have given him the benefit of the doubt. The partial vacuum which is insufficient might be as high as fifteen or twenty microns, because the range of carbon lamp vacua, so far as I have been able to determine may begin as high as ten microns.

After heating the filament he vaporizes a condensible gas (and he suggests phosphorus for that purpose) to displace the residual gas. The description is based upon the idea that you shall pump out to a fair vacuum, a partial vacuum, as stated, and then, displace the remaining gases by means of some condensible gas and thereafter condense that condensible gas so leaving presumably a high vacuum.

The practice with phosphorus is more likely to correspond with what is understood to be the Malignani effect rather than any displacement of molecules which are widely separated in a partially evacuated vessel, by putting in another gas whose molecules are also widely separated, which does not occur. One can displace gases at atmospheric pressures or thereabouts with other gases, because of the collisions which will force out the displaced gas, but when one is working in an approximately or even fairly good vacuum, this displacement does not occur in the same way.

He specifies that in any event the minimum amount of material must be used, because of the possible coloring of the globe. He refers also as prior practice to the use of mercury, iodine, sodium, potassium and arsenic by introduction and cooling, and Dwyer's improvement seems to be the use of phosphorus and of electrical heat to vaporize the phosphorus.

The complete emphasis is, as I think I indicated, on the displacement of all the gases in the tube and the subsequent condensation of the replacing vapor.

Somewhat the same comments apply to this patent as to the Malignani patent and the practical Malignani process which I also discussed in connection with the Malignani patent.

It is not a thermionic tube; there are no electrodes other than the simple lamp filament; the filament itself is not an oxidizable thoriated filament, that not even being known at the time. There is no initial low pressure, the pressure when the chemical and heating treatment are applied being high in comparison with vacuum tube pressures. The same impossibility of forming a thick film exists on account of the device being a lamp.

Tests have shown that the phosphorus which is shown as the best displacing means will prevent the activation of the thorium filament when used to get the vacuum according to the Malignani process, and there is no hint of keeping a vacuum in a lamp of this kind by Dwyer.

With reference to the prior art materials referred to at page 1, line 70, mercury, of course, has too high a pressure for use in vacuum tubes. It ionizes at room temperature under a small voltage. Iodine I have mentioned before has the same disadvantage or the same characteristic which would prevent it from being used. Sodium and potassium, two materials mentioned here, will work to attack oxygen and water vapor and clean a vacuum of those gases if it is used as described in the third patent in suit here, but it cannot be used that way in a lamp. No coating could be tolerated in a lamp. There is no suggestion that those materials be used in that way.

There is no oxidizable filament to protect and at the pressures that Dwyer used, the sodium and potassium would, I believe, be completely exhausted in any quantity that could be used in an incandescent lamp before they had carried the partial pressure of oxygen down to the extremely minute values that can exist in a thoriated filament vacuum tube without killing the emission of the filament in a very short time. Of course, there is no suggestion of any cold action, any action in the absence of heat on any of these materials in the Dwyer patent.

Q. 212. Before leaving that patent, Mr. Hogan, will you note that in the last paragraph on the second page there is a reference to the use with greater or less success, as Dwyer says, of ammonium cuprous chlorate? What have you to say as to that?

A. I have never used ammonium cuprous chlorate in connection with a vacuum tube, but I have no idea that it could be used with any effect. It would break up and give off chlorine, probably hydrogen and nitrogen, and while it might conceivably be partially useful for such a purpose as Dwyer's, I am confident that it would not protect a sensitive thorium activated filament.

Q. 213. In any event, the patentee clearly expresses a preference for phosphorus over all of the other materials mentioned in this patent?

A. Yes, there is no doubt about that. At page 2, line 131 he says: "I prefer phosphorus to other materials."

The next exhibit to which I have a reference here is a paper by Doane which is Defendant's Exhibit 11, and which appeared in the *Electrical World and Engineer* for May 21, 1904, beginning at page 963. The title is "A Resume of Incandescent Electric Lamp Exhausting." And it is an interesting running description of lamp exhaust processes as used up to that time.

It has mainly to do with mercury and phosphorus lamp exhausts as they were used in the practice. Comments on this article would add practically very little to those that I have already made as to Dwyer, since the type of exhaust treated is practically the same.

I might point out that on page 965 there is a warning that the operator has to be careful not to vaporize too much phosphorus for the reasons that I have indicated. The decrease of vacuum securable in the carbon lamps that were made with these exhausts, mercury and phosphorus exhausts, were very high compared to thermionic tube vacuums.

As I have said, ten microns pressure was ordinarily satisfactory and might be reduced to a matter of two microns in a carbon lamp.

On page 964 the Doane article refers to a preliminary mechanical exhaust prior to a chemical exhaust which brings the vacuum down to .125 millimeters which is 125 microns. The further evacuation to a satisfactory lamp vacuum being the chemical evacuation of the sort that I have described.

As to the mercury exhaust referred to, of course, we recognize that mercury in a thermionic tube is intolerable from the ionization viewpoint, both with respect to operation without disturbance by ionization as to the tube characteristic, and particularly with respect to the bombardment of the sensitive thoriated filament or mercury ions as soon as ionization voltage is exceeded.

The next citation is Defendant's Exhibit 12, which is U. S. Patent No. 946,068, issued on January 11, 1910, to Von Recklinghausen. Von Recklinghausen's proposal is to clean a mercury vapor lamp or converter referred to at page 1, line 10 to 12, by exposing heated or melted magnesium within the mercury bulb.

He puts the magnesium in a little insulating boat so as to prevent it from touching the glass walls while heated, page 1, line 39. He points out that the magnesium must be kept from coming in contact with the glass walls.

The purpose of the magnesium is given at page 1, line 77, to absorb injurious nitrogen and oxygen remaining within the container.

The pressures in a device of this sort are of course high. He refers to a very high degree of exhaustion in an iron chamber at page 1, line 80, the thought being that if iron is used the attack of magnesium on glass can be avoided. We all know from our experience with mercury vapor converters in steel casings, that it is impossible to keep even the pressures that are necessary for successful operation in the practical cases without having a pump going all the time, that is to say, a vacuum pump. Iron or steel casings will not permit a high vacuum to be held and yet such a casing is suggested for what Von Recklinghausen calls a very high degree of exhaustion at page 1, line 81.

Q. 214. The plain indication being what?

A. The plain indication being that his pressures were really high, and what he called a high vacuum would be what we would call in thermionic work or even in lamp-work a very poor vacuum.

This converter or mercury lamp is not a thermionic device, it has no filament, certainly no highly oxidizable filament; if there were such a filament as a thoriated cathode put into a chamber of this kind the mercury ionization would at once strip the thorium surface from the cathode. There is no low pressure of gases in the chamber at any time, either in its construction or operation. There is no hint in the specification or disclosure of any keeping action on the part of the magnesium. Whatever action the magnesium may have toward getting out the water vapor, nitrogen and oxygen in accordance with the desires of Von Recklinghausen is had while it is heated or melted in accordance with page 1, line 75.

There is no suggestion that a magnesium film could form in a device of this kind and the probability, in fact I think I can say the certainty is that the mercury vapor, the hot mercury vapor in a tube of this sort would attack and wash off any film of magnesium that might tend to deposit if the magnesium in the boat were vaporized rather than merely warmed or heated.

So far as I know, there is no vapor combination of magnesium and mercury. Mercury may amalgamate with cold magnesium, but any action of that sort would be slow and in any event could never do more than saturate the magnesium in a structure of this kind because of the large amount of mercury present.

Of course, the tube does operate like all mercury converters or lamps in a high pressure of hot mercury vapor and that is an impossible condition of affairs for the operation of a thermionic tube under either the first or second patents here in suit.

The next reference is Defendant's Exhibit 13, U. S. Patent 909,811, issued on January 12, 1909, to Merritt. This is a lamp exhaust patent an improvement on the Malignani patent, Exhibit 6, that I have already discussed. Merritt proposes to put his reagent on the inside of the bulb, as indicated at E in the drawing of the patent, instead of the tubular connection or tube through which the exhaust is made, the latter being the arrangement indicated in the Malignani drawing.

The only material that Merritt suggests is red phosphorus which is referred to at page 2, line 66. His purpose in putting the reagent on the inside of the wall of the lamp itself instead of the tubular tube is to avoid a blocking or sealing action which he describes. He applies heat to the phosphorus while the tube is on the pump and again after it is sealed off and he uses a minimum amount of phosphorus as referred to on page 2, line 63, and following, and at page 2, line 74, where he says that the amount shown in the drawing is greatly exaggerated.

The general effect of a little getter of this kind is that the red phosphorus, which has extremely low, practically zero, vapor pressure, is painted on, a small amount put on the lamp bulb, and when that is heated and evaporated it takes the active yellow phosphorus form and when ionized by the voltage cleans up a certain amount of gas, the ionization being accompanied by the characteristic glow of the lamp exhaust.

In that process the phosphorus returns to the low vapor pressure red form. The glow characteristic of the use of this phosphorus is referred to at page 2, line 127, and page 1, line 53. The comments which I may make on the Merritt patent are similar to those on Malignani and Dwyer and very briefly are that it is not a thermionic tube, it has no oxidizable filament, it has no low pressure, because it is a lamp only very little material can be used, phosphorus has been found to be poisonous to a thoriated tungsten filament, there is no suggestion of any keeping action in the disclosure here, and phosphorus is not useful to clean up mercury vapor of the sort that would be given off from a pump or gauge in the old exhaust process.

The next reference is U. S. Patent 859,021 issued to Soddy on July 2, 1907, and is Defendant's Exhibit 17. This patent describes a chemical pump shown in Fig. 1 at B, which utilizes the gas-absorbing capacity of very hot calcium or magnesium. References to the materials and the heating are at page 1, line 33, page 1, line 55, page 1, line 73, and specifically to electrically heating the material at page 2, line 89.

This pump is a side chamber distinct from the bulb to be evacuated and connected to that bulb through a tube with the usual constriction for sealing off. This arrangement is shown very clearly in Fig. 1 which illustrates the chemical pump in operation for the exhaustion of an X-ray tube. It is such a chemical evacuating means as that which Langmuir stated in his first patent at page 2, line 69, might be used for general pumping.

This type of calcium or magnesium pump using the vapor action, the hot vapor action, of calcium or magnesium is satisfactory for securing an X-ray vacuum or a lamp vacuum, when preceded by rough pumping. The range of pressures that lamps and X-ray tubes use at the start, are certainly not less than one micron, and in the case of the old X-ray tubes, and carbon lamps, often as high as 10 microns.

The action of a pump of this kind depends on collisions between the gas and the vap[illegible] molecules, and of course the number of these collisions is reduced rapidly as the pressure is lowered, and the spacing between the molecules that are expected to collide, increases, so that its efficiency falls off as the pressure is reduced.

It should be noted that no magnesuim or calcium will get into the tube or the lamp being exhausted, because of the construction used. The hot vapors are confined to the Soddy pump itself and would condense on the cool walls or on connecting the tube at the constriction before they get into the tube being exhausted; and of course, that is a perfectly proper and logical thing for Soddy to do, because one would not want any calcium or magnesium vapor to get into a tube that was to give off light or X-rays, that is to say, a lamp.

Now, Soddy emphasizes the heating of his magnesium and calcium and makes no suggestion of any cold action by those materials, and of course there is no suggestion of keeping action. This is a pumping process.

The pressures do not reach the low values at which the cold film keeping action of the fourth patent in suit become useful and of course there is no suggestion of any use for the protection of a highly oxidizable filament.

The next publication is Defendant's Exhibit No. 18, which is a short article signed by Frederick Soddy, and published in *Nature*, for November 21, 1907, beginning at page 53. This describes a test to determine whether the high emission from a Wehnelt cathode is independent of the perfection of the vacuum as is stated at the end of the first paragraph. Soddy used in the tube he was testing a calcium anode, and takes advantage of the hot vapor action of the pump described in his patent, to which I have already referred, as a vacuum producing means. He says that the tube was:

> "prepared in the usual way by preliminary exhaustion and washing out with oxygen to remove argon, and then subjected to the action of calcium heated in a furnace attached to the apparatus."

That phrase is descriptive of the use of his electrically heated calcium pump described in the patent, Defendant's Exhibit No. 17:

There is no reference to baking the tube and it should be noted that the tube was washed out with oxygen, in order to remove argon. I think that Soddy has stated that the calcium pump would not take out argon, and he apparently wished to get rid of it in this experiment. He does not suggest heating the lamps in connection with the patent on the pump either. He does suggest lighting the filament, but not heating the tube; and so I think that the reference to the use of the pump in the article conveys the same idea that one would get from the patent.

He then ran the tube at 1.2 amperes. Near the bottom of the first page of the article he says that:

> "The gases evolved from the anode and tube under this treatment were absorbed by the calcium in the furnace"——

And then he says that:

> "When the gases had been for the most part removed the current was passed continuously, heating the calcium anode up to its volatilizing point."

He continues:

> "Quite suddenly and completely the current through the tube stopped, and at the same moment a copious mirror of calcium was volatilized from the anode. In a little while a very feeble glow started and passed intermittently from time to time, but it was not enough to move the ammeter needle."

I might point out that he was using an ampere meter, not a very sensitive instrument—

> "and was most likely due to a further slow evolution of gas from the still heated surfaces. A current could be passed by a coil from the hot cathode to a third electrode as anode without causing any appreciable resumption of the flow in the 250-volt circuit. More gas was then generated within the apparatus by heating the third electrode with the coil discharge."

Then he goes on to speak of a repetition of the same experiment.

By Mr. Edmonds:

Q. 215. That is the cessation of the current?

A. Yes, and says that it may be—I think the implication at least is that the experiment may be repeated time and time again. He concludes that

> "in a sufficiently high vacuum, the Wehnelt electrode ceases to be effective,"

and that the electronic emission can account for no more than a negligible fraction of the total current

And he warns, at the end of his article, that it is very hard to get a good vacuum.

Under the conditions of his test, the tube glowed, and immediately after the hot calcium was released in the tube, so that the current dropped, the tube commenced to flicker again, showing, of course, visible ionization effects in both cases.

Now, I think that this article is a demonstration of the pumping action of vaporized hot calcium, both in the pump as in the case of the patent and in the tube itself; but there is no suggestion at all in the article of any cold action of calcium nor of any possible keeping action. In fact, when the mirror formed, as he describes it, the vacuum was not kept at all, but the intermittent glow started immediately afterwards. The initial pressures were high, the sort of pressure that the calcium pump itself could produce, and could not have been reduced with that construction, so far as I can see, to an extent that would be necessary to protect a thoriated cathode; and it is clear that neither the walls nor the third electrode were freed from gas, so that whatever the vacuum might have attained instantaneously it would not have remained there.

Also Soddy points out how he got the gas which made the tube glow by slightly heating his third electrode.

The oxygen wash which was used to displace the argon and other gases in the tube, that is to say, a high pressure wash at atmospheric pressure or thereabouts, would probably have left in the unbaked tube, much more than enough oxygen to destroy a thoriated filament surface, in spite of the hot calcium vapor action, and vaporization; but perhaps even a discussion on that point is gratuitous on my part, because Soddy had no oxidizable filament to be protected.

There is no more in this article than the magnesium flash clean-up or the so-called gettering action.

That is to say, the action of the hot vapor at the instant of flash, which is what Soddy utilized in his 1907 pump.

By Mr. Edmonds:

Q. 216. You do not mean magnesium, do you?

A. Did I say calcium?

Q. 217. I think you meant calcium.

A. Either calcium or magnesium or both were suggested, and I think he used calcium in this article; in fact, I am sure of it. There is no suggestion that the material had any later value, so to speak. It might as well have taken place, (that is, the vaporizing action) in the side tube, as in the case of the patent, in so far as the instantaneous flash absorption of gas is concerned, and the mirror that Soddy refers to in the article, was a secondary result, which is of no utility, either recognized or suggested by him.

In this connection, that is, in connection with the Soddy work, both as to the pump described in the patent, and the experiment described in the article, I would like to point out that Hupka, who wrote an article in the *Annalen der Physik* for 1909, which is Exhibit 21, and which I will discuss next, referred to an attempt to use the Soddy hot vapor method of evacuation, and he said that he could attain a hard X-ray vacuum by the use of calcium, but that it was not adequate for his purposes. A hard X-ray vacuum would be at the lower end of the old X-ray vacuum; range from ten down to about three microns. I think that marks about the limit of what could be done with this hot calcium process, because of course, it is convenient, and Hupka would have been glad to have used it if it had been satisfactory to go to lower pressure.

In this same connection, perhaps I should point out that pressures of the sort we have been considering, if related to oxygen, are extremely high for the action of a thoriated filament.

With respect to a comparison of lamp vacua and of non-ionization vacua, vacua in which positive ionization is substantially absent and does not interfere with the operation of the device, either by changing its characteristic, or in the case of thoriated tubes by bombarding the thorium cathode, and stripping the thorium off by that mechanical action so to speak, we have one set of conditions. But when we get to oxygen and its effects, and water vapor and its effects, its chemical effects on the filament surface, we have to adopt a new idea of pressures.

A pressure of even one one-thousandth of a micron of oxygen in a thoriated tube will oxidize the sensitive activated molecular surface so rapidly as to cause the emission to drop to one per cent. in the initial emission, in such a short time as five seconds; and if the pressure is reduced, the partial pressure of oxygen is reduced to one one-millionth of a micron, the emission will drop down to one per cent. in only about half an hour of running.

So that the amount by which the oxygen in a thoriated device, a device having an active thoriated filament, has got to be reduced, is really an astounding thing. The pressures, to get long life, are of the order of a millionth of a millionth of a micron. That is to say, the partial pressure of oxygen. One does not care, of course, to have all other gases taken down to that extent, (and probably that could not be done) because the other gases are not harmful to the sensitive surface; but the oxygen-carrying gases, oxygen itself, carbon monoxide, carbon dioxide, water, all must be excluded to a degree that is totally impossible with anything operating in the range of lamp or X-ray vacua.

Incidentally, the gases that are given out in the operation of a tube by an untreated anode, are largely oxygen and carbon monoxide, either of which would hurt the thoriated filament.

The magnesium film of the fourth patent in suit, will take up those gases, if the tube starts at a low pressure, and well below one micron, and will take them up faster than they can damage the filament; but above a micron, the space collisions become the important thing, rather than the film action, and so the keeper action of the film would seem to be applicable only to the low pressures of that general order.

Coming now to Exhibit No. 21, which is the Hupka article appearing in Volume 31, of the *Annalen der Physik* for 1909, beginning on page 169, I find the only part referred to by Dr. Chaffee, has to do with a trial of the Soddy evacuation by use of vaporized calcium in the tube.

This portion is on pages 179 and 180 of the original article, and on page 13 of the translation that we have been using, it reads:

> "I have also made experiments with the process of calcium vaporization suggested by Soddy. In one case a calcium rod connected in the circuit by a loose contact was vaporized by direct short-circuiting and formation of an arc. Another time, pieces of calcium, the size of peas, were put into a porcelain tube cemented to the vessel to be evacuated and closed at the end; this was carefully heated to a red heat by the flame of a blower. The degrees of evacuation obtained in this manner were not inconsiderable; for instance, a vessel of about one-half liters capacity was reduced from a water jet vacuum to a hard X-ray vacuum at the moment of vaporization. For the present purpose, however, this method was not adequate."

He then goes on to discuss charcoal and liquid air, but that is all there is with reference to Soddy, and Dr. Chaffee quoted only the first part of that. The point which seems significant to me is that he would not be able to go below an X-ray vacuum, and even that was attained only at the moment of vaporization.

We know that the cut-off, so to speak, of the old X-ray tube, will come in somewhere in the neighborhood of three microns of gas. That is not a hard and fast figure, because as I think has been explained, the rate of gas clean-up and of gas evolution from the electrodes in the old X-ray tube, is a differential one. There is gas coming out of electrodes and gas being cleaned up by the discharge. If we had an electrode which would not give off any more gas, then so far as the best determinations seem to go, the discharge would stop, as soon as the vacuum passed below three microns; but I say I do not want that to be taken as a hard and fast figure. It might be in one tube that it would be a two microns, and in another one, ten microns. In any event, such pressures are far too high for any purposes we are considering in this case.

I have been through the whole translation of this Hupka article, and I find no other references to a vaporizable reagent, if we can use that general term, even for getting a vacuum, much less for keeping one, and Hupka seems to have had gassy electrodes and gassy tube walls, as far as I can make out from the article. He spoke of a few sparks having been passed to one of the electrodes for cleaning it up, but of course we all recognize that that would be totally inadequate for a real clean-up of the gas operated in any metal electrode, and even when he did spark into his electrodes, the gas that he got off, whatever it may have been, was released right into the sealed tube.

He had two cemented joints in his tube, a screen, and a quartz window; and altogether the article is descriptive of an experiment that could have no bearing on any of the present inventions.

The next reference I have is the Marshall patent, No. 1,205,002, which is Defendant's Exhibit No. 28. Here again we have a variation of the Malignani process of exhausting lamps, Mr. Marshall's plan being to regulate exactly the amount of phosphorus that is to be used in each lamp. He explains that in page 1, line 40. He exhausts his lamp heated, but without lighting the filament (page 1, line 38), he seals it off, and then he lights the filament and that vaporizes the phosphorus that has been put on the end of the filament supporting stem, gives the blue glow, and then the lamp is finished. He says in the specification, page 1, line 90, that in the drawing, the showing of the amount of phosphorus used, is much exaggerated, and at page 2, line 69, he refers to the amount as a "barely discernible deposit."

On this application date of 1911, Marshall was apparently not even certain that the improvement produced in a lamp by the use of phosphorus was due to a better vacuum. He makes some rather hesitating comments as to the importance of improving vacuum by phosphorus, though I think that it is generally recognized that this phosphorus does act when ionized, as I have described, in bringing down a rough pump vacuum to a lamp vacuum.

Now, the comments that I would make, outside of the description of the invention, would be much the same as in the case of the Merritt patent, which was Defendant's Exhibit No. 13. There is no thermionic tube involved; no structure having anodes or electrodes other than the filament. There is no highly oxidizable filament. The initial pressure is very high. The same impossibility of using enough reagent to form an active film on the globe is here.

We know that phosphorus poisons a thoriated tungsten filament, and there is no suggestion of any cold action or keeping action on the part of the reagent, and it would be useless for the clean-up of mercury vapor.

Exhibit No. 32 is the next to which I come, and is an article by Kunz & Kemp in the *Phys. Zeit.* for 1912, July 1, pages 594 and 595.

This describes a spectroscopic experiment on sodium vapor, on potassium vapor, and on hydrogen gas; and the best vacuum that is suggested is as of the X-ray order, that is to say, from three to ten microns.

I have read the translation of the entire article very carefully and I can not find any justification for Dr. Chaffee's suggestion that the cathode was hot, or even partially heated, when X-rays were produced in this vacuum.

The translation reads:

> "A complete vacuum was produced so that Roentgen rays were created without heating the Wehnelt cathode."

And that particular sentence occurs in the description of the device before there is any mention of heat. So that I think it is perfectly clear that the initial investigation of the vacuum before the cathode was heated, resulted in the production of X-rays, and therefore that the vacuum was of the X-ray order.

This is confirmed by the statement which immediately follows, and which is:

> "As soon, however, as the calcium oxide electrode had been sufficiently heated, then there appeared the blue rays of electrons which spread from the cathode to the anode, however, without producing any other light."

I do not see how X-rays could have been produced with the hot cathode if as soon as the cathode was heated the glow of the cathode rays passing through the partial vacuum became visible.

Apparently Kunz and Kemp introduced sodium and calcium vapors by heating a side tube which is shown in the drawing at page 595 of the original article, but there is no evidence of any vacuum improvement as a result of that and no evidence of any higher vacuum than the X-ray values that Soddy and Hupka got using calcium. This experiment mentions sodium and potassium, but there is no evidence of any keeping action of these two materials.

Kunz and Kemp's tube was not baked and the electrodes were not heated so far as I can tell from the article and gas was apparently evolved from the walls when the tube was later slightly heated, so that I can not find anything in this Kunz and Kemp article that remotely suggests the use of the materials sodium and potassium (which are specifically named in the exhibit) for any such purpose as that of the third patent in suit.

Perhaps that sentence is not clear because it has a double clause in it. What I want to say is that although Kunz and Kemp specifically refer to sodium and potassium, and although they used those materials to determine the spectroscopic effects following the investigation of the vapors, there is no suggestion that they are improving the vacuum even on the Soddy basis of obtaining X-ray value and much less no suggestion of any keeping or cold action on their part.

The next reference in order is Defendant's Exhibit 33, which is the American Institute of Electrical Engineers' paper of June 25, 1912, by Dr. Whitney. This is entitled "Vacua," and describes the Malignani process as practically used, and as I have discussed it in connection with Defendant's Exhibit 6 and Defendant's Exhibit 13. It states the recognition of the blue glow and the high filament heat that are necessary to get the Malignani reaction.

Page 1208 of the article points out that when the vacuum had been pumped down to 30 microns and then the pump closed off, a trace of phosphorus distilled into the bulb, while the filament was very hot, a blue glow appeared, brought the vacuum down as quickly as the gauge could be read to one or two microns. That is the same order of the effects I have described in connection with the Malignani and the Malignani improvement patents. It checks with Soddy's and Hupka's and Kunz and Kemp's general order of result, although they used other hot vapors.

The Whitney article describes further the clean-up of high voltage lamps, lamps of operating voltages of 50 to 110, which is not experienced in low voltage lamps in the same way.

The article is quite a detailed discussion of lamp practice in producing vacua, but there is no suggestion in it of any cold action of a vaporizable material of any kind nor of any film action, action in film form as in the case of the third and fourth patents in suit here, nor of any keeping action.

There are some new materials mentioned, that is, new from the point of view of this case, at page 1215. About the middle of the page Dr. Whitney says:

> "X-ray tubes are usually made with a salt such as potassium chlorate or potassium hydrate, mica, asbestos, etc., in an attached side tube. This may be heated when the tube in use attains a high degree of evacuation and in this way gas is liberated into the bulb."

That of course is descriptive of the use of the so-called regulator on the old-fashioned X-ray tube, by the use of which, when the pressure in the tube had become too small for successful or regular operation, more gas could be put into the bulb by heating such material as potassium chlorate or potassium hydrate.

I mention that in connection with this Whitney paper, because potassium is a part of the name of each of those two materials, and potassium metal is one of the materials suggested in the third patent here in suit. I think it is perfectly clear that potassium chlorate and potassium hydrate are both very different things from potassium metal, and that the suggestion that gas may be evolved by heating either of those materials is a very different thing from the patented invention of using the metal films for the absorption of a harmful gas.

Potassium chlorate gives up oxygen when heated and melts at a relatively low temperature, about the same temperature at which glass softens, and potassium hydrate is used as a drier and it will give up water when it is heated after it is absorbed. It melts also at about the same general range of temperature.

That is all I have been able to find of interest in the Whitney paper, that is to say from the point of view in this suit. Perhaps I should note that the pages which I have given are the pages on the photostat I have here of a reprint of the paper, and I am not certain that the paging is the same in the transactions that are published once a year and form the collected papers of the American Institute of Electrical Engineers. Therefore, I might say that the two pages I have referred to specifically 1208, is the second page, and 1215 is the ninth page, respectively, of the article.

The next exhibit is Defendant's Exhibit No. 34, U. S. Patent 1,121,802, issued to Clark on December 22, 1914. This is hardly an electrical patent. It suggests placing a potassium or sodium coating on the interior of a lamp wall and to that extent it is of electrical importance. It puts the sodium into the tube by distillation from a side chamber as in Figure 1 or Figure 3, the side chamber being marked 2, and the vapor condenses on the wall of the lamp so that there it will act as a reflecting mirror. That is set out at page 2, line 41 of the patent and the fact that such a mirror has a high reflection coefficient is pointed out at line 100, page 1.

Clark indicates that the calcium or sodium which he proposes to use will oxidize and that therefore he must apply the coating without letting them oxidize. Reference to that is at page 2, line 5. And he does that,—he puts the alkaline metal into the tube without allowing it to oxidize by distilling it in the vacuum instead of by doing it in the open air where moisture or oxygen would spoil the brightness of the surface.

His statement is that when the alkaline metal is distilled in this way the oxygen free result that is desired, that is, the bright mirror, is had, and there is no suggestion so far as I can find in the patent of the removal of the lamp's oxygen, that is the oxygen of the air that originally filled the lamp at atmospheric pressure, except by the evacuation prior to the distillation.

Of course, there is no recognition of any keeping action on the part of the sodium or potassium mirror which forms on the inside of the wall. In fact, so far as that might occur it would dull the mirror and destroy Clark's result and his purpose. I think that this is not even remotely allied to the present case except that it does describe a mirror of one of the metals suggested, on the inside of a vacuum tube, but it could have no such effect as is necessary for the protection of a thoriated filament, which is perfectly clear from the fact that at page 2, line 114, of the Clark specification, that oil or mercury or some other liquid within the bulb is used in order to keep an open window through which the light may emerge after reflecting on the inside mirror, if anything more were needed to show that there can be no vapor free or oxygen free or mercury free vacuum within a chamber made in this way.

The next exhibit is Defendant's Exhibit No. 36, Patent No. 1,246,054, to John Clough, issued on November 13, 1917. This is a tube containing a rare gas and having an anode of calcium, magnesium, titanium, or the like, as stated in the specification. It operates at a high gas pressure. The specification page 1, line 65, points out that it should be above a pressure of several milliamperes of mercury and will more usually approach the order of magnitude of atmospheric pressure; and a specific pressure desired in the case of argon filling is given at page 2, line 11, as from five to twelve centimeters. That would be from 50 to 120 millimeters of mercury pressure.

That of course is a condition that is utterly impossible for a thermionic tube of either the first patent or the second patent in case voltages above ionizing voltages are used, because the ionization would kill the 3/2 power operation in the space charge range and would also destroy the sensitive thoriated filament.

The device of Clough is called an enclosed arc device and is that in fact. He says that it has a cathode consisting of a highly refractory material and operating at incandescence in a gaseous atmosphere, the pressures of which I have already indicated. He proposes the use of a highly chemically reactive metal such as calcium, magnesium, or titanium (this is on page 1, line 18), with a gaseous atmosphere of argon or one of the monatomic gases so as to reduce the voltage drop in the arc to what he calls a hitherto unattainable low value.

The purpose of that is to reduce the voltage that is consumed, so to speak, in the rectifier device itself; and of course in low voltage high current devices of this enclosed arc type, which is of the group that is generally characterized by the name Tungar, it is important to reduce the voltage drop and therefore the losses within the rectifier itself as far as possible.

For instance, if one is charging a six-volt storage battery with a rectifier that has a voltage drop of twelve volts, obviously the greater part of the effective total voltage of eighteen is across the rectifier instead of across the battery and consequently one endeavors to reduce voltage drop on the rectifier as far as that may be done.

The specific examples that Mr. Clough gives as to current and voltage are on page 2, line 12 and the following. The currents passed are in one instance eight amperes, in another twenty amperes, and in another ten amperes.

Those of course are high space currents characteristic of large ionization produced in gases of these high pressures. He points out that long running, forty minutes to three hours, again in this same section on page 2, will reduce the voltage drop in the way he desires and he attributes that to the action of this calcium, magnesium or titanium anode in getting rid of impurities in the atmosphere of inert gas. He says that the voltage reducing effect is entirely new and he describes the drop in arc voltage as a chemical effect of the calcium anode in the case of one of his experiments.

That reduction occurs in a high pressure tube of this kind under conditions of violent ionization and of course vapor from the calcium or magnesium anode under the heat developed at that anode will contribute to the ionization in the gas path, in the arc path, the ionized path between the two electrodes. There is consequently a possibility of the hot vapor removal of water vapor or of oxygen in much the same way as in the case of the Soddy pump where the hot vapor acted on these gases and that may have contributed as much or perhaps not so much or perhaps more, I think not so much, to the reduction in arc drop as does easy ionization of calcium or magnesium vapor.

In any event, the reduction would be to no more than the pressure of a few microns as in the case of the X-ray tubes, and that is particularly well indicated by the fact that the initial exhaust before rare gas is put into the tube, need not be done carefully. Clough says on page 1, line 61:

> "The action of the anode material makes it unnecessary to use such great care in exhaust as has been necessary formerly."

I take it from that that he would give these tubes an exhaust characteristic of the Tungar before introducing the rare gas, and that would be that they would be brought down to a matter of ten or fifty microns, so that clearly the vapor from the anode could not take up enough of the pressure of oxygen or of water vapor, beginning at even ten microns, to reduce the partial pressure to a point that would be sufficiently well cleared of oxidizing gas to protect a thoriated cathode. More would have to be done than indicated here in order to get any such result as that. Without regard to that as a matter of discussion, however, this structure has no oxidizable filament to protect. The cathode is not of a thoriated type. There is, as I said, no low initial pressure, nor any careful exhaust, and consequently there is no possibility, and of course, no suggestion of any keeper action in a tube built in this way. Yes, that finishes that part.

THE COURT: Ten o'clock tomorrow morning.

(Whereupon at 6 P. M., an adjournment was taken until Friday, November 5, 1926, at 10 o'clock A. M.)

U. S. District Court, Wilmington, Del.,
Friday, 5th November, 1926,
10 o'clock A. M.

SEVENTEENTH DAY.

Before:
Hon. Hugh M. Morris,
U. S. District Judge.

Appearances as before.

Mr. Davis: I wish to state that it is not the intention of the plaintiff to recall Dr. Arnold for further cross-examination with reference to the notebooks, and so forth, provided that defendants will agree to keep these various notebooks available to us; and we understand, of course, that they will be returned, and that we may take such extracts or photostat copies of specific pages as we may need, and that when our witness desires to testify about what he finds in these notebooks the defendants will stipulate that these are the books that they purport to be.

Mr. Haight: Our position regarding these books, if your Honor please, is this: The books have not been proved and cannot be used in evidence without proof, or without our consent. We have no disposition, however, to prevent the use of such part of the books as the plaintiffs may want to use, provided we are notified now, or before we depart for the week-end, of the parts that they want to use, and the reasons why they think that they are relevant and material to the issue in this case.

Mr. Davis: I am sorry that I shall be unable to give that notice today in detail. It will be physically impossible to do it.

Mr. Haight: Well, I suppose if we have notice on Monday, it will be time enough.

Mr. Richmond: I cannot answer that, because I do not know how big the proposition will be, but we will do the best we can.

Mr. Haight: I do not want to ask Mr. Davis to do an impossible thing. I thought probably they had the thing lined up if he was going to be in Court today.

Mr. Richmond: There is a stack of these books that high (indicating), and our opponents know a lot better than we do what is in them. They have had them from an hour to a week, as we have been able to get them here for them, so that it is hard for me to answer more definitely than that.

(Further Discussion.)

Mr. Haight: I do not want your Honor to be under a misunderstanding. Both sides have furnished each other with documents and papers as requested, and we have done that as a matter of decent practice of law.

The Court: Surely. That is the reason I hope you ignore——

Mr. Haight: And the only question now is whether these notebooks are admissible in evidence. Now, we say that they are not admissible, but we have not any objection to the other side using them, provided they tell us what parts they want to use, and point out the relevancy or materiality of those parts, so that we will be in a position to explain or rebut them, if we deem it advisable to do so.

Mr. Davis: I think perhaps under the circumstances it is proper that I should withdraw the statement that I am not going to cross-examine Dr. Arnold because I propose to get what I want out of those notebooks, if I have to subpoena people from New York to testify about them.

Mr. Haight: You see if that is done, that will give us the very thing that we feel that might be given to us the other way. All that we want is not to bludgeon in the dark, that is rather——

The Court: I had no thought that counsel will not be able to continue as they have begun.

Mr. Davis: We will do all we can, if your Honor please, but we have been under great pressure for a long time.

Mr. Davis: I ask that defendant's counsel stipulate that the Coolidge patent No. 1,211,091, issued January 2, 1917, and referred to in the history of the Arnold patent, which I offered in evidence yesterday, that the stipulation be that the application for that patent was filed in the United States Patent Office, October 28, 1915.

Mr. Darby: You ask us to stipulate. Very well, subject to correction.

Mr. Davis: And in the same manner, and subject to the same correction, stipulate that the application for the Coolidge patent, No. 1,211,092, January 2, 1917, was filed June 5, 1915.

Mr. Darby: It is so stipulated, subject to correction if error appears.

Mr. Davis: If your Honor please, Dr. Coolidge is here and my friends on the other side——

Mr. Haight: What about Mr. White?

Mr. Davis: We have now two witnesses on the stand, but I would like to have Dr. Coolidge go home today. I think defendants would like a little time after his direct, to look at the notebooks, and perhaps get ready his cross-examination, and I thought they would prefer I put on Dr. Coolidge first, that is all—anything they like.

Mr. Haight: That is agreeable.

The Court: Then very well; let Dr. Coolidge be sworn.*

John V. L. Hogan, resumes the stand.

Direct Examination (Continued).

By Mr. Edmonds:

Q. 218. Mr. Hogan, will you continue your answer to the last question? You have reached, I think, the patent of MacKay?

A. That is correct. The next reference to be considered is, I believe, the last one on the list contained in the question, and is Defendant's Exhibit No. 37, which is a patent No. 1,208,597, issued to MacKay on December 12, 1916. This has to do with enclosed arc rectifying devices of the sort referred to in the Clough patent discussed at the end of the session yesterday. The drawing is much the same, the difference being that the anode in MacKay is made of tungsten or carbon, as explained at page 1, line 54, and that on the heavy wire lead supporting the filament, there is placed, as shown in the drawing by reference number 9 on Figure 1, a wrapping, so to speak, of magnesium or calcium. Another way of putting the material into the tube is suggested in Figure 2, where a capsule is shown at the top of the tube. This invention of MacKay's has to do with the operation of a high pressure gaseous atmosphere rectifier, specific reference to the pressures occurring on page 1, line 78, and the following, for instance, where it is stated that argon at a pressure of about 5 to 12 centimeters of mercury is found suitable.

---

*For examination of Dr. Coolidge, see page 1495.

Q. 219. That is what, in microns?

A. 50,000 for 5 centimeters. This patent is, like the Clough patent, directed toward decreasing the arc voltage drop in a device of this kind, so as to improve its efficiency. The conditions of operation, are, of course, impossible for a thermionic tube, because there is so much ionization that space charge would be destroyed. In fact, it is only by the destruction of space charge that the extremely high current flows through such a device. Also, the filament, if it were of thoriated tungsten, would be destroyed by ionization, as soon as a voltage above ionization values was applied. The preparation of the tube involves evacuation and the filling with a suitable gas at a considerable pressure. I think the comments I made as to the Clough patent in this same connection, would apply here.

Now, MacKay says on page 1, line 63; that:

> "Removal of water vapor from the bulb by heating the bulb during evacuation is desirable, but not so necessary as when no chemical addition is used."

He suggests at page 1, line 23, the use of non-metallic absorbents, such as phosphorus pentoxide instead of the alkali earth metal, calcium or magnesium, and evidently considers them equivalents, and says that they have no affinity for the gaseous filling, but are chemically active with respect to impurities in the gaseous filling.

That is stated at page 1, lines 24 to 26 in connection with the discussion of the desire to produce a markedly lowered voltage drop or loss in the arc, as stated at the beginning of the first paragraph. The end of that paragraph points out that where argon is used, the most deleterious gaseous impurities tending to increase the drop of potential, appeared to be water vapor, hydrogen and nitrogen. The only one of those three that affects the thoriated filament, which we are considering, is water vapor, by reason of its oxygen, although of course above ionization potentials, bombardment by either of the other two gases might make trouble.

The MacKay specification on page 2, line 20, points out that the arc apparently activates the gaseous impurities, so that they combine more readily with the chemical agents within the bulb; and it is perfectly clear from the disclosure, that he relies upon or considers necessary this arc heat or the highly active state of his contained materials which result from the high temperature at which this sort of device operates in the discharge path, the ionized path.

I suppose that even starting with a rough exhaust of the sort that would be used here or in the Clough case, the partial pressures of oxygen or water vapor might as the result of the process described here, go as low as a few microns, or perhaps even lower than that; but I see no possibility of those pressures going down to anything like the order that we have to have with a thoriated tungsten filament, in order to prevent oxidation of its highly sensitive surface, and consequent destruction of this high emission. Of course there is no suggestion in the MacKay patent of any cold action on the part of any of the materials contained, whether calcium or magnesium, which are specifically used in the fourth patent in suit, or of phosphorus pentoxide, MacKay's alternative that is of no value in connection with thorium emission at all, and there is no suggestion in MacKay of any film keeping action as the result of his use of any of the three materials that he proposes.

I do not believe that any such film-keeping action or cold action can be expected at pressures of the order used by the MacKay. Such pressures and temperatures as are used by him, that if a film should occur on cooling, for example, when the arc is started positive ion bombardment from the arc would sputter the film or vestiges of the film to a vapor, and we would be back where we were before to that hot vapor clearing out impurities for the purpose of reducing the arc drop. The emphasis on page 1, line 93, is on the heating in MacKay, and page 1, line 88 on the vapor, and he gives as his examples a six-ampere arc in argon with phosphorus pentoxide, giving a drop of thirty to forty volts ordinarily reduced to about ten volts, when a small quantity of phosphorus pentoxide is used in the tube.

That example occurs on page 2, beginning at line 37, and continuing to line 44.

A second example of a neon-filled tube is given, in which the arc drop is reduced from about fifty volts down to about twenty volts, by supplying metallic calcium in the tube. Since the stated purpose and the practical value of the MacKay invention is the reduction of the arc drop, it is clear that the phosphorus pentoxide which brought the voltage drop down to ten volts, on a six-ampere tube, would be preferred to calcium which brought it down to twenty volts only in a similar six-ampere tube, one being used with argon, and the other with neon.

I believe, now, Mr. Edmonds, that I have covered all of the citations given in your question.

By Mr. Edmonds:

Q. 210a. Before you leave the MacKay patent, will you explain the statements appearing on the second page at line 20, with respect to the function performed by the arc in developing the activity of the gaseous impurities?

A. The sentence is:

> "Apparently the arc activities the gaseous impurities, so that they combine more readily with the chemical agents within the bulb."

That is the sort of reference I spoke of as to the necessity of heating from the arc, or perhaps positive ions from the arc, but in any event the creation of an active state in which these desired combinations proceed in such a way as to reduce the arc drop.

Of course, there is another possibility there. I think I referred to that in connection with the Clough patent, and the emphasis on the action of the arc itself, rather strengthens that.

The point is that the reduction in arc drop may be very largely due, and perhaps almost entirely due to the relatively easy ionization of the vapors from the materials put in. Of course, that is a function, which, while useful in a device of the Clough or MacKay type, would be exactly the sort of thing one would not want in a pure electron thermionic device, or a device operating with a thoriated cathode.

Q. 211a. Will you next consider the White patent, No. 1,159,307, Defendant's Exhibit No. 42, in this case, and state what bearing you find that patent to have upon the third and fourth of the patents in suit, if any?

> MR. EDMONDS: I do not know whether your Honor will recall this patent or not (handing paper to Court).
>
> THE COURT: No, I do not.

A. The White patent, No. 1,159,307, describes an electrical discharge device which is, as stated at page 1, line 14: "My Improved Detector." That is to say, a device utilized for the conversion of radio waves into a form that will operate a normal indicator, and so give a response, for instance, in a telephone receiver.

The improved detector is stated in the same paragraph to be similar to the DeForest audion, and also similar to the vacuum tube device of the Langmuir patent, or of the Langmuir application, No. 795,610, which I believe resulted in the first patent in suit here.

The first long paragraph in the specification, constituting practically the whole first column of page 1, describes the common features of both devices. They are treated as the three-electrode type of device from the point of view of this patent and are rather completely described here. White points out in the second column that the detection sensitiveness of a Langmuir tube may not be sufficiently high to give the best possible response.

He states that, as based upon "asymetry of current flow," beginning at page 1, line 58, and he says beginning at line 65, that the device, that is to say, the Langmuir device, "is more especially valuable as a relay or amplifier of such oscillations." Then he states that if a certain amount of residual gas be present in the tube the operation of the device becomes quite different, and he goes on to describe the audion, pointing out at line 79, that there is a limit to the voltage which may be used in the circuit of the audion, because as the voltage increases ionization of the gas in the tube increases, a blue glow appears followed by deterioration of the electrodes, disengagement of more gas therefrom and finally the destruction of the operative qualities of the tube.

He explains thereafter that the voltage is made as high as possible consistent with avoidance of those limitations, and explains the principle of operation of the audion in that a decrease of potential on the grid causes a decrease of current in the plate circuit and *vice versa*, and your Honor may recall that that fundamental explanation of the way in which the audion operates was that which was put out by Armstrong and adopted thereafter by most of the people including White.

He says that the result is that when high frequency oscillations are impressed upon the grid their presence is made known by a decrease of current in local or plate circuit, and that is the normal operation of the audion detector.

Then he continues on page 1, line 104, stating that he has found that by maintaining within the evacuated container of a device of the general nature already described, that is to say, a three-electrode tube, a certain definite pressure of gas which in amount is very much less than that which is necessary to make the so-called audion operative, and not greatly more than would be tolerated in a device such as disclosed in the Langmuir application, very remarkable results are secured in the relations which then exist between the current in the plate circuit and the voltage on the grid.

That is to say, he proposes the use of a definite and small amount of gas or vapor in a tube which has previously been cleaned and made a perfect Langmuir tube so to speak. He says, beginning at page 2, line 6, that, with this definite pressure of gas or vapor in the device, he has found that the variation of current in the plate current with variation of potential circuit on the grid follows the law of a pure electron discharge tube such as that of the Langmuir application, except within a small range of voltage the plate circuit. Page 2, line, 13, reads:

> "Within this small range there appears to be a condition of instability such that when high frequency oscillations are impressed upon the grid there always follows a sudden decrease of current in the local circuit."

That is later described with reference to a sudden drop or kink in a characteristic curve, which kink is at a definitely restricted point of the characteristic. As one increases the voltage it results, because of the steepness of current change at that point, in a much greater detector sensitiveness than would be secured in a Langmuir tube.

Beginning at page 2, line 35, White says that while his improved detector is dependent upon the presence of a small but definite gas pressure in the space including the electrodes, its operation is not accompanied by blue glow or any other well-recognized evidences of positive gas ionization, and

> "The amount of gas or vapor present is perhaps not more than one-tenth of that which characterizes the so-called audion."

The next paragraph, beginning at line 44, describes the sudden change in plate current to which I have already referred, and then beginning at line 55 of page 2, White says:

> "In producing and maintaining the desired gas pressure in my improved device it is not sufficient to leave in the tube a certain amount of residual gas during exhaustion, since this gas does not remain constant in amount but generally will decrease upon operation of the device by the well-known cleanup action, though in some cases the amount of gas present increases rather than decreases, due to other causes."

That of course refers to a possible attempt to clean the tube and the electrodes and then to leave within the tube a certain amount of gas during exhaustion and White warns against that, since he says it will not be steady and the clean-up will reduce the gas and he says in some cases the gas pressure will increase to an unwanted extent due to other causes.

Those causes are necessarily incomplete bake-out or incomplete preparation of the electrodes within the tube.

Then he continues at line 64 of page 2:

> "To secure the necessary definite gas or vapor pressure in the tube, I therefore provide a substance with the desired vapor pressure and place this in the tube. Among other things I have found that amalgam is suitable for the purpose. Mercury alone appears to be unsuitable, as it has too high a vapor pressure at ordinary temperatures though by lowering the temperature of the mercury the desired vapor pressure may be obtained."

In other words, White wants a certain amount of gas in his tube, gas or vapor, it makes no difference from the ionization point of view which it is. He wants to get a certain definite and controlled amount of ionization, which will produce a certain irregularity at some part of the characteristic curve and this increases the sensitiveness of the device as a detector when operated at that point.

Of course, such a discontinuity or irregularity would work against the use of the device as a quantitative amplifying apparatus, for instance, but it is desirable for increasing the sensitiveness in the detector condition.

White says that he cannot rely upon residual gas, not completely exhausted, and so he proposes cleaning the tube completely and then putting in a substance with the desired vapor pressure such as amalgam.

An amalgam is simply a piece of metal which alloys with mercury or which mercury will wet and which has as a result of the alloying action a somewhat lower vapor pressure than liquid mercury alone would have at any given temperature.

I am not sure what the range of pressures attainable by the use of amalgams may be, although I can look that up, but I think it is easily possible to produce metal amalgams of mercury which have pressures of the order of one-tenth of that of mercury itself for the same temperature.

The remainder of the second page of the specification is a detailed description of the structure and at the beginning at the top of page 3, more information about this introduced substance is given at line 5 and the following:

> "Before the envelop is sealed off there is placed in it (in a manner hereinafter described) a small amount of vaporizable material 17, for example, an amalgam, sulphur, phosphorus pentoxide, tungsten hexachloride, and in general substances having a suitable vapor pressure at the operating temperature of the device."

He then goes on to warn against substances having too high a vapor pressure such as mercury, but to indicate that they may be used if a low temperature is maintained as in a side chamber. That is of course a practical thing to do although inconvenient.

He says at line 16 that gases at the proper pressure will give the desired effect, but the effective pressure and possibly also the character of the gas are changed by some chemical or electro-chemical action in the tube, so that gases act only temporarily. That is another reference to the change of pressure of which I spoke.

Again referring to the material 17, either loosely placed in the main envelope, page 3, line 21, or placed in the side chamber, he states, at page 3, line 23:

> "The character of this material depends upon the temperature and voltages at which the device is operated, as will be hereinafter explained, its purpose being to maintain in the space, vapor at a definite low pressure."

Following that is a description of the evacuation of the device and the formation of the amalgam within it by the introduction of mercury vapor and its subsequent condensation before the seal-off and after evacuation.

Then occurs the statement on page 3, line 79, that a device thus prepared will operate at ordinary room temperatures with a substantially pure electron discharge between anode and cathode without positive ionization, even when the impressed voltage is as high as three to four hundred volts or even higher.

However, when the voltage between cathode and anode is within a certain range an irregularity is observed in the electron discharge current as already described.

That portion ends at line 88 and is a more detailed description of the kink in the characteristic to which I referred.

The circuits are described in the next two columns and then beginning at page 4, line 51, White says:

> "On either side of the region of greatest sensitiveness indicated by the off-set of the curve 18 of grid potential, the characteristic of my device, is substantially that of a pure electron discharge. The vapor pressure necessary to produce this peculiar effect varies with the character of the material used."

He then states the sort of pressures which he wishes to obtain in his tube by the introduction of these amalgams or the other materials.

> "For mercury vapor in the type of apparatus illustrated the pressure should be between the limits of .00006 and .00040 millimeters of mercury."

This corresponds from six one-hundredths to four-tenths of a micron of mercury. Continuing at line 61 for the case of sulphur he says that it operates best at a pressure of from two-tenths to three microns of mercury. He then goes on to describe the operation of additional circuits.

THE COURT: You come now to the conclusions?

THE WITNESS: Yes.

THE COURT: We will defer that until the next session.

MR. HAIGHT: It is stipulated that the original of such of defendant's Exhibits Nos. 100 to 278, inclusive, offered in evidence in this case and listed on pages 935 to 947, inclusive, of the record, as are reproduced in the Interference record, need not be produced and filed with the clerk, but that in lieu thereof, the copies of such exhibits embodied in the Interference record may be considered as the original exhibits in this case and marked by the clerk accordingly.

And it is further stipulated that the original of such of Plaintiff's Exhibits Nos. 20 to 161, inclusive, offered in evidence in this case and listed on pages 928 to 934, inclusive, of the typewritten record, as are reproduced in the Interference record, need not be produced and filed with the clerk, but in lieu thereof, the copies of such exhibits embodied in the Interference record may be considered as the original exhibits in this case and marked by the clerk accordingly.

(Whereupon at 5 P. M. an adjournment was taken to Tuesday, November 9, 1926, at 10 o'clock A. M.)

U. S. District Court, Wilmington, Del,
Tuesday, November 9, 1926,
at 10 o'clock A. M

EIGHTEENTH DAY.

Before:
Hon. Hugh M. Morris,
U. S. District Judge.

Appearances: As before.

Mr. Edmonds: Now, Mr. Hogan.

John V. L. Hogan, resumes the stand.

Direct Examination (Continued).

By Mr. Edmonds:

Q. 212a. Mr. Hogan, will you complete your answer to the last question, concerning the White patent?

A. I think I had already pointed out at the end of the specification that Mr. White said, page 4, line 51, that his tube operated like the Langmuir tube of the first patent, except at the kink in the characteristic curve which was produced by the additional gas, and also that at page 4, line 60, he points out that when mercury is used, he desires a pressure of from six one-hundredths of a micron up to four-tenths of a micron, of the specially added vapor, and that when sulphur is used, he may desire from two-tenths of a micron to three microns.

This White tube is then a detector tube which is produced by introducing into the tube a definite pressure of gas or of vapor. Before the gas is introduced, the tube is prepared as would be a Langmuir tube of the first patent here in suit.

The introduction of the gas or vapor at the definite pressure destroys the smooth and regular operation of the tube at one part of the voltage range. The vapor may be introduced by a vaporizing material, such as sulphur, mercury, amalgam, of which White spoke, and that particular material or the alternative materials to which he referred, gives off a definite amount of gas.

Putting in that material then instead of improving the vacuum of the Langmuir tube of the first patent, as is the case with the magnesium or the alkali metal of the third and fourth patents, that is to say, instead of taking out or reducing the partial pressure of oxygen, or water vapor, or carbon monoxide or carbon dioxide, here White increases the pressure and prevents a clean-up.

If this device should be used with a sensitive thoriated tungsten filament, the bombardment of positive ions, even if not the vapors themselves, would shorten the emission by knocking the thorium off the filament, even if they were operated considerably below the blue glow point, because the kink or irregularity in the characteristic is based upon the presence of a definite amount of ionization which is produced by the introduction of gas-giving materials.

In that connection I have a curve that gives the vapor pressures of mercury, sodium, potassium, and magnesium in a range of temperatures from zero degrees Centigrade to 300 degrees Centigrade. That shows in the upper left-hand corner a high pressure corresponding to a micron of mercury at about room temperature. The ranges chosen by White are indicated on this sheet. Then at considerably lower vapor pressures come the potassium and sodium curves and finally the magnesium curve with a very much lower vapor pressure at considerably higher temperatures.

I have also made a tabulation of the temperatures in degrees Centigrade that are necessary to attain specific vapor pressures for these five materials, mercury, potassium, sodium, magnesium and calcium. Four pressures have been chosen, one one-thousandth of a micron, one one-hundredth, one-tenth and one micron and perhaps the quickest way to handle this would be to give the tabulation to the reporter and put it into the record at this point. I want to comment that the amalgams will come a little below the mercury but are above the potassium with respect to the scale.

(The tabulation referred to by the witness is as follows):

Temperatures in Degrees Centigrade to Attain Specific Vapor Pressures.

Pressure	Mercury	Potassium	Sodium	Magnesium	Calcium
0.001 micron	—43°	64°	83°	260°	416°
0.01 "	—27°	83°	112°	300°	468°
0.1 "	—7°	118°	150°	346°	524°
1.0 "	18°	153°	192°	398°	592°

Mr. Edmonds: Curve produced by the witness is offered in evidence.

(Received in evidence and marked "Plaintiff's Exhibit No. 176." *See Volume IV, Plaintiff's Exhibits, page 129.*)

By Mr. Edmonds:

Q. 213a. Referring now to the Defendant's Exhibits, Nos. 39, 40 and 41, these being the patents of New Zealand, Australia, and Great Britain, I find referring for example to the New Zealand patent the following passage:

> "The evacuation of the tube preferably while still heated is carried out by means of a suitable evacuating means, for example, a Gaede molecular pump, which removes vapors as well as gases. Chemical evacuating means such as electrically vaporized calcium or magnesium may also be used."

This last sentence, and I think the next one as well, is common to all three of the patents. Will you explain to the Court the meaning of that last sentence?

Mr. Darby: I object to that. The patent speaks for itself.

The Court: Will you read the question?

(Q. 213a was repeated by the stenographer.)

The Court: I see no word or phrase or sentence there that needs interpretation. I may be mistaken about that and consequently I will overrule the objection. Unless there is, I think it goes beyond the expert's testimony.

Mr. Edmonds: I did not think your Honor would know whether this is an additional step or a substitutional step.

The Court: It is on that basis that I overrule the objection.

Mr. Darby: As I understand from Mr. Edmonds' last statement, the witness will draw his own conclusions and advance them. As I understand, Mr. Edmonds admits that the question is not directed to explain any word, phrase or technical expression.

The Court: If it is a construction of the patent, whether it is in the record or not, I cannot tell what it is until he gives it. While expert testimony in its proper field is exceedingly helpful and indispensable, when it goes into the judicial field it is of no help.

A. The reference to chemical evacuating means such as electrically vaporized calcium or magnesium, which may also be used, is a reference to such a calcium or magnesium furnace, electrically heated——

Mr. Darby: I object to that. There he is going outside of an expression in the patent. He refers to some other kind of means not described in the patent.

The Court: That is on the border line, I think, Mr. Darby, and I will not strike it out.

A. (Continued.) Such an electrically heated calcium or magnesium furnace as we discussed in connection with the Soddy patent last week. The use of that may be in addition, and as Soddy proposed it, it was in addition to another pump. That is to say, the use of electrically vaporized calcium and magnesium is an additional evacuating means over and above the rough pump.

By The Court:

Q. 214a. The patent says that?

A. It says "may also be used." I think the natural way to read it in view of Soddy is that a rough pump would be used first and calcium and magnesium additional.

Q. 215a. I gather from the reading of the words of the patent, it was an alternative and not an addition.

A. It may be taken either way and I am not positive as to which. I think that the use of calcium and magnesium furnace was always in connection with a preliminary pumping.

Q. 216a. But the patent is not clear as it is there?

A. That is correct.

By Mr. Edmonds:

Q. 217a. I call your attention to the two photographs, Defendant's Exhibits No. 70 and 71, of the Lamont pumps and the testimony of the California witnesses concerning them, and particularly the matter of technique of using them in evacuating tubes. Using these pumps and that technique, will you say what would be the character of the vacuum of a tube exhausted by means thereof?

A. This pump with its use of mercury, without any means of excluding it, without any effective exclusion of water vapor, without adequate baking of the bulb, and without any heating of the plate or grid of the tube, other than that incidentally secured by the gas-heating of the bulb, would necessarily result in producing a tube of the typical DeForest audion type characterized by a low-power limit and irregularity of operation. If sulphuric acid were used in the bulb E of the pump, oxygen-bearing vapors would get into the tube and affect both the ionization and a filament there, and if phosphorus pentoxide were used while it is a useful drying agent, it gives off oxygen gas, and that would be present in the tube.

Q. 218a. If an attempt were made to use a thoriated tungsten filament in a tube evacuated by means of these pumps, and this technique, would thorium emission be realized?

A. No, I am quite certain it could not, because of oxygen-bearing gas and oxygen itself, in addition to the bombardment that would follow in such a tube.

Q. 219a. Would you say in a word, Mr. Hogan, whether there would be any essential difference as between such a tube as Lamont is said to have evacuated by means of this apparatus and technique, and on the other hand, the regulation DeForest audion of 1912?

A. No. I think there would not. I think Lamont simply made audions which were of fair performance.

Q. 220. Referring to a vacuum tube said to have been operated upon by Lamont, defendant's witness Hewlett testified that it was customary to put in his station, a variable B-battery ranging from forty to seventy volts. His testimony continued:

> "The voltage depended upon the degree of exhaustion of the particular tube I had in use, and I would say it ranged around about 60 volts but I had a glass beaker with a thermometer and the tube in the oil of this beaker, and by lighting a small alcohol lamp under this beaker, I could some-

> what control the amount of B-battery used for best results . . . heating the tube lowered, the amount of B-battery used on the tube . . . the filament of the vacuum tube was lit to a brilliant incandescence, and the filament was controlled by a small rheostat from a suitable battery."

Will you say what effect upon the tube or its vacuum, the heat in the oil bath had, Mr. Hogan?

A. That is exactly like the tube heating that was commonly used by radio operators in the early years of the audion. The heat applied to the glass walls results in disengaging gas within the tube and therefore increasing the gas pressure in the tube and reducing the voltage at which a blue glow can be had, and also the operating voltage of the tube. A blue glow at sixty to seventy-five volts shows in the ordinary audion construction with a gas pressure of something like four to six microns.

Q. 221. The defendant's witness Beck testified that when filaments were replaced in Lamont's shop, the replacement filaments were of tungsten, and that "they acted just like wire," that she "could handle the tungsten just like the wire, and could bend it in shape," that she "actually did bend it," and that she knew the replacement filament was tungsten wire "because it was not carbon." Will you state if, in your opinion, this testimony points to the use of tungsten wire at all?

A. Well, from the fact that tungsten filament taken from a lamp is extremely brittle, I think that that could not have been tungsten. Tungsten filament from the spool, before it goes into a lamp, is bendable, but once it has been heated in the vacuum, even for the aging run at the factory, and after the use of the lamp in normal service, the filament becomes brittle so that it would not bend like wire. Tantalum, on the other hand, will bend in that way.

Q. 222. Then you agree with defendant's witness Lamont in the statement that "it is next to impossible to re-shape the tungsten filament"?

A. Yes, if the filament is taken out of a lamp.

Q. 223. Witness Hyde testified to the practice of exhausting a vessel by means of a pump, and the use of manganese dioxide in a side tube connected with the vessel. I call your attention to his answers to XQs. 2 to 11, and ask you to state what would be the degree and quality of the vacuum resulting from this practice.

A. This was a side tube chemical pump used in addition to the mechanical pump, and I think not always used, as I remember Hyde's testimony. With manganese dioxide heated in such a side tube, he might be able to get a useful X-ray vacuum of from three microns up to ten microns, but there would be no chance at all of his getting a low pressure and particularly a partial pressure of oxygen-bearing gases corresponding to what is necessary for the last three patents in suit here. Tests of manganese dioxide as a pumping agent used in this way have shown the impossibility of activating a thorium filament in the vacuum thus produced.

That probably is due because managnese dioxide when it is heated apparently gives off enough oxygen from the compound to poison the thoriated filament and then does not reabsorb in cooling enough to prevent that poisoning. It is a relatively poor chemical pump.

Q. 224. The witness Hyde also testified XQ. 59, that he "made changes on the pump that made it possible to obtain a vacuum, without use of any chemical agent, equal to rotary oil pumps used at the present time and roughly to a vacuum of four to six microns."

Say in a word whether a thoriated filament could be operated to realize thorium emission in such a vacuum.

A. No, it could not. That is an X-ray vacuum.

Q. 225. Defendant's witness Beale testified to the use of DeForest audions at Q. 11 that according to his recollection, "There was a defined distinction between detector tubes and amplifier tubes in the fall of 1912." Have you any knowledge on that point?

Mr. Darby: I object to that. The testimony refers to a distinction in the Federal Telegraph Company out in California.

The Court: The statement as made by Mr. Edmonds is too general?

Mr. Darby: Yes, sir.

By Mr. Edmonds:

Q. 226. Just limit the answer to the question to your own knowledge of the conditions existing in that year entirely apart and outside of the affairs of the DeForest Company in California.

Mr. Darby: I object to that as immaterial.

The Court: I will hear you, Mr. Edmonds, because as I understand the status of the evidence from Mr. Darby, it would not meet the evidence put in by Mr. Darby.

Mr. Edmonds: I think that quite apart from meeting that evidence specifically as to what was the practice in the Federal Company's place, it would be proper for us to show that in the general use of these audions, that there was no distinction recognized at all or if there was a distinction to show what it was.

The Court: That would be evidence meeting defendant's case generally and not meeting the evidence specifically.

Mr. Edmonds: Yes, sir.

The Court: Let me hear the question.

(Q. 226 was repeated by the stenographer.)

The Court: Do you want to reframe that question?

By Mr. Edmonds:

Q. 227. Entirely without reference to Beale, will you state whether there was any such thing as a recognized distinction between detector tubes and amplifier tubes of the DeForest type in and about 1912?

Mr. Darby: I object to the form of the question, because by inference it has some bearing on Beale and the Federal Telegraph Company.

The Court: I think your objection is well taken. Do you want to still reframe it?

Mr. Edmonds: Yes, sir.

Q. 228. In 1912, was it so far as you are aware, the practice in the use of the DeForest audions to distinguish between some of them and others of them with respect to their use as detectors or amplifiers?

A. I do not know what the custom was in 1912, since we had no DeForest amplifiers in the East at that time. I do know that when DeForest came East in 1913, the distinction— —

Mr. Darby: I object to that.

The Court: Sustained. This part of the answer is not responsive to your question.

By Mr. Edmonds:

Q. 229. Let me ask you if it was common to use DeForest audions of different types with respect to their vacua for detection or amplification?

Mr. Darby: When?

Mr. Edmonds: In and about 1912.

A. I cannot answer that as of 1912, though I can, as of the few years following.

Q. 230. Please do so.

A. The amplifier tubes so-called were tubes of the double plate type and the detector tubes were tubes of the single plate type. The pressures in both types were substantially the same, that is to say, the variation from tube to tube of either type was greater than the variation from one type to the other. I base that statement on measurements of pressure that I have made on DeForest tubes which I purchased in 1914 and 1915.

By **The Court**:

Q. 231. Which has the double plate?

A. The amplifier.

By **Mr. Edmonds**:

Q. 232. You said that there was no essential difference between the DeForest tubes treated by Lamont and the DeForest tubes as made by McCandless; placing them together in one category, will you say how they compared in operation, behavior, and characteristics with, for example, the plaintiff's UV or UX-201-A tube such as Plaintiff's Exhibit 17?

Mr. Darby: I do not know how far afield we are getting. I understand that the witness has testified as to his opinion as to the Lamont tube built on the Lamont pump, but I do not believe that he has testified as of his own knowledge of any Lamont tubes that he himself has used, and I do not see how he can answer this question unless he has had experience with the Lamont tubes.

Mr. Edmonds: The witness has said that the Lamont re-exhausted tubes were essentially the same as the regulation DeForest audion of 1912, and I am grouping those two tubes and asked the witness to compare that with the tube before your Honor in this suit.

The Court: I do not think it is helpful at all. But should there be anything that may be helpful you can be protected by your cross-examination.

Mr. Darby: I do not know whether to move to strike out in view of your ruling or not, but the witness proceeds to state that this is matter that has already been covered in the testimony and then he proceeds to state that the DeForest tube, by inference at least, carried back to the Lamont tubes, was not reproducible and what-not, and this witness is in no more position to testify to that than I am. I will not move to strike it out.

Mr. Edmonds: I think he is.

Q. 233. Will you please make the comparison with respect to the matter of the economy of use, assuming that use to be in connection with radio?

Mr. Darby: I renew my objection.

(Discussion.)

The Court: I will overrule the objection.

A. The old DeForest audion amplifiers which I bought and used had a filament power consumption under normal conditions of about 5½ watts, that is to say, with a voltage of 3½ applied to the filament, the current was about 1.6 amperes which represents a heating power for the DeForest amplifier tube of 5.6 watts. The 201 type filament, which is the pure tungsten filament tube, put out by the plaintiff here, from something like 1920 and before the thoriated filament tubes were put on the market, had a power consumption at normal adjustment of five watts, that is to say, one ampere flowed through the filament at five volts. Although the power consumption was approximately the same as of the DeForest amplifier tubes that I bought from DeForest, and which I have measured myself. The performance of the 201 tube was considerably better, because of its improved design.

Now, the 201-A tube in which the thoriated filament of the second patent here in suit was incorporated, and similarly in the defendant's D V-5 tube, which followed it on the market, the filament power consumption was reduced to one and one-quarter watts, that is to say, only one-quarter of an ampere at five volts. Therefore, one could run four of the new thoriated filament tubes at the same filament cost as he could run one of the old 201-A tubes or old DeForest amplifier tubes.

Q. 234. You do not mean the old 201-A tubes?

A. The old 201 pure tungsten filament tubes or the old DeForest tubes, and at the same time get a better performance. Now, that saving in filament power, while it is small per tube, is tremendous when considered in the aggregate, as covering, for instance, the number of sets used in the United States. It represents a saving to the radio users of the United States, those who are now using 201-A tubes with thoriated filaments instead of 201 tubes, for instance, with pure tungsten filaments, a saving of certainly millions of dollars per year, and I think well over ten million dollars per year. That follows from the thoriated filament construction, and of course is in addition to the longer filament life and the possibility of reactivation and also ruggedness and freedom from burn-out, which are characteristic of the thoriated filament. I might say also that while that has to do specifically with the second patent, the low pressure necessary to get the activated thorium filament could not have been attained if we had not at first gotten as far down as necessary for the ionization free operation of the first patent in suit.

Q. 235. You have referred, Mr. Hogan, to having made purchases of DeForest tubes in 1914. Did you keep abreast of the development of the DeForest tube thereafter, and have you down to date, and can you express that evolution as briefly as possible? I mean now, down to the time of the advent of the D V-5 tube which is complained of in this case?

A. Yes. I have kept in touch with the development of the DeForest tubes. In 1912, the structure as shown by Exhibit 7-A here, is of the same type as McCandless continued to make in 1913 and 1914.

Mr. Haight: May I interrupt you just a minute, Mr. Hogan? I do not know whether I was listening to the objection and to your Honor's ruling a minute ago, and maybe my objection has already been covered by some ruling, but it does not seem to me to be proper for this witness to testify as to his knowledge of the development of the DeForest audion. He can not at the best have more than second-hand knowledge. We have in the evidence the first-hand knowledge.

The Court: I think he had primary evidence of it.

Mr. Haight: He can not know what Dr. Arnold did, or Langmuir did.

The Court: Not at that time.

Mr. Edmonds: We will cure that in a moment, sir. Of course, you understand, Mr. Hogan, I am talking about DeForest audions as put out by DeForest's various companies——

Mr. Haight: I understand then this is limited to the audions put out by the DeForest Company?

Mr. Edmonds: Including this defendant, the DeForest Radio Company, is it? The same corporation under its earlier name, the DeForest Radio Telephone & Telegraph Company.

Mr. Haight: That is the same company.

Q. 236. That is the same company, generally speaking, the companies with which DeForest was identified regardless of the name?

A. Yes, sir, that was my understanding of your question.

Q. 237-38. Yes.

A. The tubes in 1914 which I bought were of the same general type as those which I now know were put out in 1912 and 1913. The two specific kinds were the detector which had the single filament and plate and used about three and a half volts on the filament, with a current of about one-half ampere, and the amplifiers which had the double filament and plate and used about 3½ volts, and 1.6 amperes. I have a copy of the DeForest 1914 bulletin, B-14, entitled: "DeForest Audion Detector," which refers to both the detector and the amplifier bulbs and contains some instructions and comments on their use. Do you want me to quote from this circular, Mr. Edmonds?

Mr. Darby: The only objection I have is to its relevancy and materiality.

The Court: Where is it pertinent, Mr. Edmonds?

Mr. Edmonds: I think it is very pertinent to show, if the Court please, in view particularly of the assertion which the defendant makes on the California evidence, just what it was that DeForest and his companies had subsequently to the time when they say, he made something pertinent to the patents in suit. Your Honor was not advised during my brother Darby's argument that there is a defense of prior knowledge and use by DeForest in California, and throughout this California testimony, DeForest's name appears, as in the correspondence in evidence, so that he is linked up with this testimony.

The Court: You may finish your answer.

The Witness: On page 2, second paragraph, under heading "DeForest Detector Type R. J.-5" has as its second sentence:

> "The battery switch at the left of the lamp, and the rheostat lever are then moved to a position where signals are at their best."

This refers to the double adjustment, both of filament current and of the B-battery potential, which was necessary with the gassy audions of that time.

The last paragraph on the page headed "Audion Bulbs for Renewals," reads:

> "The sensitiveness of audion bulbs has been still further improved of late. We make two grades, the 'S' or Standard, and the 'X' or extra sensitive. Audion bulbs are sold only as renewals or to those who have purchased our audion receiving sets, and then only on the return of the old bulbs."

And then follows a price list for the two bulbs. At page 3, the last paragraph, under "Instructions," it says:

> "If too much 'Battery B' voltage be applied a blue glow will appear in the bulb, or may be seen merely around the edges of the 'plate' or wing. When this blue glow fills the bulb it is usually not very sensitive. The glow can be removed by simply reducing the B voltage by the 3-point switch on the RJ-4 and the 6-point switch on the RJ-5. The sensitiveness can be instantly restored by merely switching off and on the lighting current. Only one filament should be burned at one time. This doubles the life of the bulb."

And on the fourth page, the third item from the end towards the last:

> "Audion Bulbs, double grid and double plate, for renewals only."

Following the listing of amplifiers, those are the amplifier bulbs to which I refer, and those instructions are characteristic of the use of the bulbs which I bought and used in 1914 and 1915.

Q. 239. I think you are going to refer to some subsequent bulletins, Mr. Hogan. Will you do so briefly?

A. I have now Bulletin B-15 of DeForest audion detectors, variometers and the time receiver, which is a 1915 Bulletin and shows the same types of tube. Page 2 in the second paragraph says:

> "When once the proper voltage and heating currents are determined, no further adjustment is required."

This refers to the double adjustment, both of filament current and plate voltage as before. The third paragraph from the last on page 2, says:

> "The battery 'B' is located inside the case and is composed of a number (from 10 to 12) of three-cell flashlight dry batteries."

On page 4, the fourth paragraph as to the DeForest audion detector R. J.-5, reads:

> "If too much battery 'B' voltage is applied in any Audion Detector, a blue glow will appear in the bulb, or may be seen around the edges of the plate or wing, and a roaring sound will generally be heard in the telephone receivers. When this blue glow fills the bulb it is usually not very sensitive, and if this discharge is allowed to persist for a time, the bulb will become 'hard,' and will require a higher battery 'B' voltage."

And further:

> "A 'hard' bulb can be 'softened' by heating very carefully and evenly over a flame for a few minutes."

Page 7 in the directions for the DeForest audion time-receiver, the fourth paragraph reads:

> "Now start the switch B at the lowest point 12, and turn to the right until a blue discharge occurs in the audion bulb, or a hissing noise occurs in receivers. Bring the switch back one point at once, as the blue discharge, if prolonged, is detrimental to the bulb."

A photograph on page 10, showing the combined audion detector and single step amplifier, shows the filament rheostat controls and the Battery B switches separately for each of the two tubes. That is to say, the contact points forming a semi-circle at the right of each bulb adjust the B-battery for the particular bulb and the rheostat knobs are between the bulbs and the battery switches and a little above a separate rheostat being provided for each bulb. This is referred to on page 11 at the end of the third paragraph from the bottom, which says:

> "Each bulb has its individual control switches, B 1 and B 2 control each battery 'B,' and each bulb has its own rheostat lettered OUT and IN."

The very last sentence on page 11 is:

> "Two separate 'A' batteries are required for this instrument."

Showing the necessity of individual and careful adjustment for each of the two bulbs. On page 14, the third paragraph:

> "Audion bulbs are furnished in two styles—those of standard degree of sensitiveness (Style 'S') and those of especial sensitiveness (Style 'X'). Every bulb is given two tests before leaving our factory, against a standard. Amplifier bulbs are supplied only in 'X' grade, in tantalum filament and Hudson or tungsten filament types. The latter types have from two to three times the operating life of tantalum filament bulbs."

Q. 240. May I interrupt you there, Mr. Hogan? By Hudson type filament, you were familiar with that, were you?

A. Yes.

Q. 240a. And that was a filament of pure tungsten, with a spiral wire of tantalum around the loop; is that correct?

A. Yes. Page 15, the second part of the price-list is headed:

"Renewal audion bulbs," and gives prices for the two types of detector bulbs, Type "S" and Type "X," and the two types of amplifier bulb with tantalum and Hudson filament. This is the 1915 Bulletin.

In 1916, the same line of round audion bulbs was continued, and in addition a tubular audion bulb type "T" was put out. This is referred to in Bulletin C-16, page 3, as to the directions for using, under the subheading "Caution." Paragraph 4 says:

> "4. Adjust rheostat to give normal filament brilliancy and adjust Battery B switch to best point. Then try reversing current from the lighting battery to find out which direction is better.
>
> "5. The bulb is most sensitive at a point just below that at which the hissing sound is heard in the telephones."

This tubular bulb requires the characteristic adjustment of the gassy tubes.

Q. 241. Is this type "T" DeForest audion a tube of the character described and listed in the C-16 catalog?

A. Yes, that is stamped D.F. on the plate and has the DeForest label. There were several similar types put out by other manufacturers. Your Honor can see the grid through the opening in the plate, and the straight filament there.

THE COURT: Yes.

A. (Continued.) In 1917 and 1918, the war years, the DeForest Company made the V. T.-21 receiving tube, using about 3.6 volts on the filament, with a current of about 1.1 amperes.

In 1919 and 1920, they put out the so-called VT which had the standard Navy base, the four-prong base which was adopted during the war, and which used a filament current of about 8/10 amperes and about four volts filament potential. I believe they also sold to the public during 1919 and 1920, some surplus VT-21 tubes. Their catalog B headed "Post-War Models," of September, 1919, shows the new DeForest VT audion on page 19, and this is described as follows:

> "This tube is identical with the latest forms of tubes manufactured by the DeForest Radio Tel. & Tel. Co. for war work and is similar in shape to the V. T.-21 tube of which the DeForest Company made thousands for the Signal Corps during the war. In the United States its sale is restricted to amateurs and experimenters for reception only.
>
> "The tube consists of a highly evacuated vessel cylindrieal, rather, than bulbular, in shape enclosing the three elements, grid, plate and filament, in the form of the old type T tubular DeForest tube with which amateurs are familiar. The plate is of nickle, cylindrical in shape and surrounds a helical grid also of nickle. The filament is a crimped tungsten wire passing through the center of the grid exactly as it did in the old style T type DeForest tube. The chief difference between this tube and the type T tube of similar mechanical construction is in its evacuation. The old style type T was an ionic or gaseous tube, very unstable in operation and requiring a variable 'B' battery. It had the decided disadvantage that after continued use the tube would get 'hard' and require more 'B' battery until it reached such a state as to be inoperative. The new 'VT' tube, like the DeForest standard tubes today, is purely an electronic tube exhausted to a very high vacuum, so that it is nongaseous and will stand very high plate potentials. When used as a detector, however, a battery of 20 to 40 volts is sufficient to give the proper plate current although voltages of 80

> to 100 may be used without detrimental effect upon the tube. The 'B' battery, moreover, is not critical in adjustment and, therefore, a fixed battery may be used and is used for all practical work."
>
> "The filament takes from .75 to .8 amps. only, whereas the old type T tube required about double this amount. This is a decided advantage in that it saves charging of the storage battery at short intervals. A 4-volt storage battery will light the filament, but a 6-volt battery with a control rheostat will give better results. The filament is of crimped tungsten and tests show that the majority of these tubes will burn from 1000 to 2000 hours."

Then under the instructions on page 21:

> "These instructions apply to the new type high vacuum tube such as was used by the U. S. Army and Navy and is at present being manufactured by the Moorehead Company exclusively for the DeForest Company under the latter's patents. The Marconi Company are sole distributors for us. The old type gaseous tube with the candleabra base can be used similarly, except that a variable 'B' battery of from 20 to 50 volts is required The gaseous type tubes are, however, no longer being maufactured."

And the third and the last paragraph:

> "Connect a fixed battery of from 20 to 60 volts into the plate circuit."

Your Honor will recognize the type T tube as that which I spoke of in connection with the 1916 circular, and also the change in operation occasioned by elimination of the variable B-battery that was necessary for the gaseous tube, and is not necessary for the hard tube of this 1919 type.

The sale of these VT's was continued into 1920 and I believe into 1921. About December, 1922, DeForest brought out a new DV-6 tube which had a cylindrical bulb and a 4-prong base, but had its grid plate and filament elements horizontal. This used a tungsten filament with a rating of three to five volts and of one-half to .7 ampere. In January, 1923——

Q. 242. May I interrupt a moment? Do you happen to know at what time the plaintiff's UV-201-A and 199 were produced?

A. Yes. Those got on the market about January, 1923.

Q. 243. Will you now proceed with your answer?

A. Yes. They were the thoriated filament tubes.

Q. 244. Such as the plaintiff's tube in evidence in this case?

A. Yes, that is correct. The DeForest Company, about April, 1923, put out the DV-6-A tube which had filament characteristics similar to those of the 201-A, except I think the filament current was rated somewhat higher. That tube had also a thoriated filament and the magnesium keeper. It had the horizontal elements similar to the DV-6.

It is shown in a DeForest circular, marked catalogue L in the lower left-hand corner of the cover, beginning at page 21, and carrying over to page 22. The second paragraph on page 21 points out that these tubes are of the so-called hard or gas free type, and that because of this they are stable in their operation. The small filament consumption is emphasized and here the filament rating is given as five-tenths of an ampere, which is at five volts and is higher, twice as high, as that used in the 201-A.

In September, 1923, the DeForest Company put out the DV-1 tube or at least it was available on the market in September, it may have come out shortly before, and that had a thoriated tungsten filament and a magnesium keeper and was like the Radio Corporation UV-199 as to filament consumption, three volts and six one-hundredths ampere, though it had a standard size base instead of the small base characteristic of the 199.

They also put out about that same time the DV-2 which was like the 201-A tube, with filament rating five volts and one-quarter ampere. It had a standard base, tubular bulb, thoriated tungsten filament, magnesium keeper and a plate voltage rating of 90. The plate and grid filaments were boxed like as in the case of the 201-A.

Sometime in 1924, the DV-3 tube with the same filament ratings as the UV-199 was available and then in 1925 came the DV-5 tube, which is like the 201-A and has a filament rating of five volts and one-quarter ampere, a normal filament temperature of 1925 degrees K. and a plate voltage rating of 125 volts.

Q. 245. Have you stated the normal filament operating temperature of the 201-A?

A. The 201-A is rated I think at 135 volts for amplification. I have forgotten that.

Q. 246. The normal operating filament temperature?

A. The normal operating filament temperature is 1925 K.

Mr. Edmonds: With the consent of the opposing counsel, instead of introducing these original circulars, I wish to introduce photostat copies of them, they being first the DeForest Bulletin of 1914 as Plaintiff's Exhibit 177.

(Received in evidence and marked "Plaintiff's Exhibit No. 177." *See Volume IV, Plaintiff's Exhibits, page 130.)*

Mr. Edmonds: DeForest Bulletin of 1915 as Plaintiff's Exhibit 178.

(Received in evidence and marked "Plaintiff's Exhibit No. 178." *See Volume IV, Plaintiff's Exhibits, page 134.)*

Mr. Edmonds: The DeForest Bulletin of 1916, as Plaintiff's Exhibit 179.

(Received in evidence and marked "Plaintiff's Exhibit No. 179." *See Volume IV, Plaintiff's Exhibits, page 149.)*

Mr. Edmonds: And the DeForest Company Catalogue L of 1922——

The Witness: I do not know the date of that, but it refers to the DV-6-A tube.

By **Mr. Edmonds:**

Q. 247. Which would bring it about April, 1923?

A. Yes, I think this was a 1923 catalogue. It is not dated.

(Received in evidence and marked "Plaintiff's Exhibit No. 180." *See Volume IV, Plaintiff's Exhibits, page 153.)*

Mr. Edmonds: The DeForest Catalogue of 1919, as Plaintiff's Exhibit 181.

(Received in evidence and marked "Plaintiff's Exhibit No. 181." *See Volume IV, Plaintiff's Exhibits, page 156.)*

Mr. Edmonds: And finally the DeForest tube T audion referred to by the witness as Plaintiff's Exhibit 182.

(Received in evidence and marked "Plaintiff's Exhibit No. 182.")

Mr. Edmonds: You will agree, Mr. Darby, that these catalogues and bulletins which have just been offered in evidence were put out by the defendant company at or about the dates referred to by the witness.

Mr. Darby: I agree to that subject to correction if error be made to appear. I know they are all catalogues put out by the DeForest Company, but as to the dates, I do not like to stipulate, because I do not know whether it is a fact myself.

Mr. Edmonds: And there is no dispute between us as to the type T audion which I have just introduced, being a production of the DeForest Company.

Mr. Darby: I do not know that that is made by the DeForest Company, but I believe it was. The reason I make that reservation is because at the time these tubes were put out there were a number of counterfeit tubes manufactured which opposing counsel have been aware of and as far as I can go is that this type audion is a type of the DeForest type T.

Mr. Edmonds: And that it represents in every respect the DeForest type T audion.

Mr. Darby: Yes.

Mr. Edmonds: I would like to mention to your Honor one fact, and that was referred to by my brother Darby in opening for the defense. He was explaining how it was that testimony was taken in San Francisco, that is now being used in this case, and explained to your Honor that it was taken in other cases brought in the Eastern District of New York under the three patents before your Honor. I want to add to that that the Brooklyn case against the DeForest Company under the second and third patents here in suit was brought in May, 1924, and under the fourth patent here in suit in April, 1925, that is correct, Mr. Darby?

Mr. Darby: Yes, sir.

By Mr. Edmonds:

Q. 248. The Wehnelt cathode has been several times referred to in this testimony. I will ask you to explain briefly and generally the construction and operation of that cathode and compare it with a thoriated tungsten cathode operating in the environment in which that cathode is used as for instance in the plaintiff's tubes?

A. The Wehnelt or oxide coated cathode dates from about 1904, when Wehnelt proposed to coat a platinum strip with calcium or barium or strontium oxide and he used that as a cathode. One method of preparation was to paint on a paste of the oxide, and another was to dip the platinum wire into a nitrate solution and oxidize the calcium on the wire itself.

There was a good deal of difficulty in getting uniform oxide coatings on the strips, and the cathodes made and used in the old experimental devices showed a decrease in emission with time in addition to the nonuniformity. A good deal of work was necessary to make a practical oxide cathode from the types that were in experimental use up to 1912 and 1913. Even today with the best oxide cathodes, a great deal of care is necessary in their handling as compared to the thoriated tungsten filament, for instance.

One part of the evacuating process that I believe has been mentioned in Dr. Arnold's testimony has to do with the "opening up" of the Wehnelt cathode. That is to say, as put into the tube it does not show high electron emission and it has been found necessary to bombard the cathode itself with positive ions while the tube is on the pump, watching it very carefully, because as soon as the filament starts to emit its emission gains very rapidly and unless the current is taken off or reduced almost immediately the filament burns up. It is a very tricky step in the preparation of a Wehnelt cathode, this "opening up" proposition.

In general, the Wehnelt cathode both as to the filament and as to the tube containing it costs more than a similar tube using the thoriated tungsten. That is largely because of the better exhaust required in order to get satisfactory operation from the Wehnelt cathode. More time is required on the pump and more care in the exhausting process and there are more rejected tubes, I believe.

The matter of cost is also affected by the matter of convenience of manufacture. The Wehnelt cathode wire must be kept away from the air until it is used. The thoriated tungsten wire is used right from spools. There is more breakage I believe, in the case of the Wehnelt cathode, because bending breaks off the coating unless it is very carefully done.

The thoriated wire is considerably more rugged and stands higher cleaning temperatures and Wehnelt oxide covered wire as used today, I think, has a melting limit or at least a dissociation limit at about something one and a half times above the rated voltage; that one cannot go above a low voltage across the filament without making it so hot as to almost if not quite destroy it, whereas thoriated wire may be overloaded something like four times without burning it out; that is to say, 400 per cent.

In operation the coated wire (following that same thought of cleaning) will burn out at a voltage where thoriated filament will not. That is a definite practical advantage to the user who may accidentally put a high voltage across the filament and does do so quite frequently.

At the same filament efficiency I think the lower current and higher voltage that are characteristic of the thorium filament give greater freedom from battery troubles and contact resistance troubles in series with the filament circuit. The amplifying power of the tube using thoriated tungsten filament is more nearly uniform throughout its life. The low current limit that you can get with a thoriated tungsten filament you cannot get with the Wehnelt cathode and that makes possible the power socket operation with reasonably cheap rectifying apparatus, that is, in connection with present-day receiving sets operated from the wall outlets.

On life, the reactivation possible in the thoriated tungsten filament I believe gives it an even longer life than can be had from the Wehnelt cathode. The Wehnelt cathode well made, will last longer (and considerably longer, often) than the first activation of the thoriated filament, but with the successive reactivations in good vacuum I believe that the total thoriated filament life can be extended considerably longer. In any event, there is no marked difference except possibly in favor of the thoriated cathode, as to life. I think that generally summarizes the differences between the two types of filament.

Q. 249. Will you tell us to what extent the practice of reactivating the thoriated tungsten filament of the plaintiff's tube obtains today and has in the recent past?

A. Since the thoriated tungsten filaments came on the market and the reactivating process became understood there has been a quite wide growth of the sale and use of so-called rejuvenators, and reactivators and reconditioners. Those are usually little transformers arranged for alternating current operation from the light socket and fitted with a control switch and a tube socket, sometimes also fitted with a meter, and so arranged that a tube which has either had thorium removed by excessive heating, for instance, by putting the B-battery current accidentally through the filament, or which has attained a low emission in normal use, may be put into the reactivator and given both the flashing or cleaning treatment which is accompanied by reduction of thoria to thorium at a high temperature, and then (by throwing a switch the other way) the activating heat treatment that brings out the thorium from the inside to the surface of the cathode.

There are something like a dozen or more makes of reactivators advertised and a number of radio stores make a practice of reactivating tubes for the customers and making a charge for that.

I have used two types of reactivators, one the Sterling and one the Hemco. The Sterling is an alternating current instrument and the Hemco is good for either one (A. C. or D. C.). The calibration of the Sterling, shows that the cleaning and reducing temperature corresponded with 16.3 volts across the 201 A. C. filament and that represents a temperature of 2775 degrees K. The activating voltage gave 2170 degrees K. and in this same device a checking position or voltage corresponding to the operating voltage of five volts is also provided so that the emission can be read on a small meter under the operating condition and that corresponds to a temperature of 1925 degrees K.

The directions with the activator were to operate at the high voltage, which corresponds to 2775 degrees for thirty seconds and then to activate at the medium voltage 7½, or 2170 degrees K. for from two to ten minutes or until the test voltage shows good emission.

Q. 250. Does this circular which I show you, purporting to have been published by the Sterling Company, illustrate the Sterling reactivator to which you refer?

A. Yes, sir. That is the instrument. This type of device, all these devices, are useful only with the thoriated cathode tubes, because that is the only type of tube which can be reactivated.

Mr. Edmonds: I offer the Sterling catalogue in evidence as Plaintiff's Exhibit 183.

The Court: In the absence of objection it is admitted.

(Received in evidence and marked "Plaintiff's Exhibit No. 183." *See Volume IV, Plaintiff's Exhibits, page 161.*)

Mr. Edmonds: I offer in evidence Exhibit 1, being a sketch made by the witness Hewlett as Plaintiff's Exhibit 184.

(Received in evidence and marked "Plaintiff's Exhibit No. 184." *See Volume IV, Plaintiff's Exhibits, page 165.*)

Mr. Edmonds: That is all of the direct, for the second case, and I understand, if the Court please, that Mr. Darby is ready to cross-examine the witness on the testimony as thus far given relating to the last three patents.

Mr. Darby: I do not know whether that is exactly the case. Your statement is perfectly right but the thought occurred to me that inasmuch as this witness's testimony up to the present time has been confined largely, if not entirely, to the last three patents in suit, if it would be of assistance or advantage to your Honor to have the cross-examination of this witness on the last three patents appear at this part of the record.

The Court: Any way.

Mr. Darby: Both Mr. Edmonds and Mr. Davis and myself have agreed that for our purposes it would be better, if it is entirely satisfactory to your Honor.

The Court: All right. We will take our short recess.

(After a short recess.)

Cross-Examination.

By Mr. Darby:

XQ. 251. In connection with these DeForest bulletins, Mr. Hogan, what type of tubes was it that you bought from the DeForest Company or DeForest tubes which you bought in 1914?

A. The round bulbs, both of the detector and amplifying type. I cannot say as to 1914, that I got double-plate tubes, but I got both types in 1914 and 1915.

XQ. 252. What were the type numbers of the tubes that you got?

A. I do not believe there was any type numbers.

XQ. 253. Were there any type letters?

A. No, I do not believe there were type letters. There was the S-grade and the X-grade detector which was the single plate tube, and I had both of those, though I think I bought X grades mostly; and then on the amplifier tubes there were no types other than the designation tantalum filament, or Hudson filament and I had both of those.

XQ. 254. And separate B-batteries were recommended for use in connection with the different uses of the tube, that is, when they were used as a detector and amplifier in the same equipment, separate B-batteries were employed?

A. I do not remember as to 1914 and 1915, but I do remember as to 1913, that the DeForest Company put out a three-stage amplifier in which each of the three tubes had separate B-batteries.

XQ. 255. I am not referring to the amplifier, but to the detector as distinguished from the amplifier and call your attention to catalogue B-15, page 10?

A. There is one detector and one amplifier shown and each has a separate battery.

XQ. 256. And in this catalogue B-15 there is one paragraph at the bottom of page 2, reading as follows:

> "All our audion detectors are regularly furnished with standard 'S' grade audion bulbs. The 'X' grade will be supplied at the additional prices as given in the price list in this bulletin."

That is correct?

A. Yes, the X-grade was a more sensitive bulb.

XQ. 257. And the bulletins did not state in what respect the X-grade and the S-grade differ from each other?

A. No. Except as to sensitiveness. They state that clearly.

XQ. 258. Then, in catalogue B at page 21——

A. I have not got that, Mr. Darby.

XQ. 259. You read from it?

A. Yes, I gave Mr. Edmonds my copy to put in evidence.

XQ. 260. On page 21 you read: "Connect a fixed battery of from 20 to 60 volts into the plate circuit and in series with the telephone receivers." And from the context of what you had read theretofore it appears that that was contained as part of the instructions for using the DeForest audion of the new type high vacuum tube; is that correct?

A. That is correct, except that later in the paragraph it speaks of a similar use of the old type.

XQ. 261. What was the significance of that statement "Connect a fixed battery of from 20 to 60 volts into the plate circuit and in series with the telephone receivers," which caused you to read it into the record?

A. That is a reference to a fixed battery.

XQ. 262. From twenty to sixty volts?

A. Yes, depending on the use.

XQ. 263. And it is your understanding that those instructions were with reference to a hard or high vacuum tube as distinguished from the gaseous tube?

A. I think it makes it clear that the B-battery need not be adjusted with respect to the hard tube. It must be chosen as to the use.

XQ. 264. My question was, it is clear in your mind that those instructions to connect a fixed battery of from twenty to sixty volts were part of the instructions in connection with the use of the hard vacuum tube as distinguished from the gaseous tube?

A. Yes, I think that is correct.

XQ. 265. And on the same page reference is made that the tubes were being manufactured by the Moorehead Company exclusively for the DeForest Company under the latter's patent and the Marconi Company are sole distributors for us. What Marconi Company did you understand that to be?

A. I think that was the Marconi Wireless Telegraph Company of America.

XQ. 266. The same company who were then within the limitations contained in the statement of Mr. Davis, were the predecessors of the Radio Corporation?

A. I do not know what those limitations were, but I do know that the Marconi Company turned over part of its business to the Radio Corporation.

XQ. 267. In other words, we are talking about the same Marconi Company?

A. I think so.

XQ. 268. Are you familiar with the methods now employed in manufacturing vacuum tubes?

A. I am familiar with some of the methods.

XQ. 269. Are you familiar with the automatic exhaust machines?

A. I have seen some of them in operation, although there is a good deal of variation there.

XQ. 270. Very briefly, see if we can agree on this, that the way the vacuum tubes today are generally made where the automatic exhaust machines are employed, is to first initially or partially exhaust the vacuum tube on the exhaust machine and then seal it off; is that correct?

A. I think you have to go further than that to give a good picture of the process. Before seal-off the tubes are quite well exhausted in the process I have seen.

XQ. 271. What do you mean quite well? To what degree of vacuum?

A. Probably——

XQ. 272. A micron?

A. Or less.

XQ. 273. A micron or less?

A. Yes.

XQ. 274. But in that process they are using thoriated tungsten filament, are they not?

A. Yes.

XQ. 275. Then will you tell me, as I understood your testimony that a micron of gas contained in a vacuum tube would be far too high a pressure for use of the thoriated tungsten filament, is that correct?

A. That is correct, if that was an oxygen bearing gas.

XQ. 276. After they seal off the tube from the exhaustion machine, say with roughly one micron of gas in it, they thereafter flash the magnesium, do they not?

A. I think that the magnesium in some processes——

XQ. 277. The point I am trying to make——

A. Just a moment, Mr. Darby. The manufacture of the 201-A tube with which I am familiar vaporizes the magnesium and degases the plate before the tube is sealed off.

XQ. 278. Before the tube is sealed off?

A. Yes. Therefore——

XQ. 279. You are not familiar then with any process where they seal off before they vaporize the vaporizable reagent?

A. No, I have not seen that in a factory.

XQ. 280. Do you know that that is being used?

A. No, not of my own knowledge. I have heard so.

XQ. 281. As I understood you a minute ago you stated that you were familiar with the process where the pump produced a vacuum equal to about one micron——

A. I said one micron or better.

XQ. 282. All right. Before it was sealed off. And with the thoriated tungsten filament. In the process that you are familiar with, what means if any were taken thereafter to decrease the gas pressure in the tube?

A. None with respect to the oxidizing gases, that is to say, the partial pressure of the oxidizing gases including water would be as far down as it was necessary to go before the tube was sealed off; that is to say, below a one one-millionth of a micron. As to the non-oxidizing gases a so-called filament or gas clean-up was used and that probably reduced the pressure from something of the order of one one-hundredth of a micron or something better. It is hard to say.

XQ. 283. My information is that the plaintiff company in manufacturing some of its tubes here in evidence uses an automatic exhaust machine, exhausting the interior of the tube down to one micron or thereabouts, in some instances even higher, and after the tube is sealed off from the machine, flash the vaporizable reagents to thereby obtain the necessary degree of vacuum. Are you from your own knowledge in a position to tell me whether that is correct or not?

A. No, I am not, but I think it is very unlikely.

XQ. 284. You do not know of your own knowledge?

A. No.

XQ. 285. Do you see any reason why it could not be done?

A. I think that the vaporizing of the calcium or magnesium would give off a good deal of gas that should be taken out in the pump and I do not think it would be as good a process as to flash, so to speak, while on the pump.

XQ. 286. Do you think that that process employed would obtain a high enough degree of vacuum required by Patents Nos. 2, 3, and 4 in suit?

A. I do not know. Perhaps if you will let me say that the degree of vacuum of 2, 3 and 4 is a matter of the purity in general, I could add that probably the magnesium flash would clean up the oxygen bearing gases even though the tubes were off the pump, but it may at the same time release other gases which would give ionization trouble but I cannot be sure.

XQ. 287. They certainly would be sufficient—the process I outlined to you certainly would be sufficient to take care of any oxygen containing gas?

A. I said I thought that likely.

XQ. 288. You know the affinity between thorium and oxygen is very high, do you not?

A. Yes. That is to say, thorium is easily oxidized.

XQ. 289. And I also believe you stated that tungsten, even thoriated tungsten, after it has once been heated thereafter becomes very brittle; is that correct?

A. The heated filament in a lamp is stronger from some points of view than the unheated filament, but it is not so ductile. It is brittle. It will break off short.

XQ. 290. When it is heated again, however, it is ductile in part at least while it is still hot, that is, it can be bent without fracture; that is a fact, is it not?

A. I have not tried that, but I know if you heat a filament in vacuum you can bend it.

XQ. 291. And you do not know that the same is not true in open air?

A. I do not know at what temperature you have to heat the filament.

XQ. 292. I am not asking you about the temperatures. If you heat it like you heat a tungsten filament so that you can bend it?

A. The point is that——

XQ. 293. Can you answer that question first?

A. No, I cannot.

XQ. 294. You do not know?

A. No, except as I have already stated.

XQ. 295. Did you consider in the reasons that you advanced to the Court in considering the testimony of Mrs. Beck whether or not Mrs. Beck when she bent the filament had heated it?

A. No, I think the statement read to me was that it could be handled like wire.

XQ. 296. And you based your testimony on that statement which was read to you?

A. That and the other portions read to me.

XQ. 297. You did not look through the testimony yourself to ascertain whether or not she stated anywhere that when she bent it it was hot?

A. Yes, I read the testimony but I do not remember any statement of that sort.

XQ. 298. And therefore your testimony is based on that?

A. Yes.

XQ. 299. Would your testimony have been different if you found in there that Mrs. Beck stated that she had heated the filament while she was bending it?

A. No, I think not, because——

XQ. 300. All right, that is all I want. As I understand it, without knowing whether or not heating it would permit it to be bent, you came to the conclusion that it was not tungsten that Mrs. Beck employed, merely because she said she could bend the filament?

A. No, that is not quite a fair statement. I do know that you can bend tungsten under proper conditions and at a high enough temperature even though it has been heated before. What the conditions were for Mrs. Beck I do not know except as she stated she could handle it like wire and she knew that it was tungsten or thought that it was tungsten because she knew it was not carbon. I thought that all of that was insufficient to show that it was tungsten and the description was much more likely to indicate the use of tantalum by her, tantalum lamps being available on the market until early 1914.

XQ. 301. My point is, as I understood you, your conclusions would not have been modified or altered in any respect if you had taken into consideration the fact that she had heated the tungsten while she was handling it?

A. Not by the simple statement that the tungsten was heated, that is correct.

XQ. 302. We all know that incandescent lamps, which I believe you had pointed out, have very poor vacuum, some of them, when they are in their unlighted condition, it is very easy to break the filament if it is made of tungsten by a slight jar, that is correct?

A. Your introductory statement was not correct, that is to say, tungsten filament lamps may have a very good vacuum after they have been used for some time.

XQ. 303. Let us take an incandescent lamp in use less than 100 hours.

A. Even then the vacuum may be good. It is very difficult to tell what the vacuum is after a lamp has been sealed off.

XQ. 304. Then you disagree with Mr. Langmuir in his 1915 article that after 100 hours you can get a very good degree of vacuum. You believe you can get it sooner than that?

A. You have two variables there. There is no sharp cut-off at 100 hours and there is no statement in your question as to what is a good vacuum. What I am trying to say is that a lamp grows harder in use and does not decrease in pressure all at once. That is all.

XQ. 305. Now, having made that statement will you answer my question as to whether or not we all know that a tungsten lamp, after it has once been heated, can thereafter have its filament broken by a relatively slight jar to the lamp while the filament is in an unlighted condition?

A. Yes, I think your point is that it takes ordinarily a harder blow to break the filament when the filament is lighted than when it is not.

XQ. 306. Yes.

A. I think that is general experience.

XQ. 307. And do you attribute that to the fact that the filament is more elastic when it is hot?

A. I would say that it was stronger. It would not break so easily.

XQ. 308. Would you not say that it is more elastic?

A. I do not know. "Elastic" is much misused as a word.

XQ. 309. In discussing the Merritt Patent 909,811, you stated that the only material Merritt suggests is red phosphorus, Merritt referring to a vaporizable reagent. I notice that the Merritt patent says, line 61:

> "Upon the inner walls of the bulb itself, as at *e*, there is deposited a small and preferably definite amount of some one of the well-known agents suitable for chemical exhaustion, such, for example, as red amorphous phosphorus."

Can you tell me what were some of the other well-known agents suitable for chemical exhaustion as of the date of that patent?

A. Merritt was 1909 and refers to a Malignani improvement, so to speak, and so I suppose we should go back to the Malignani patent which specifies in 1895—

XQ. 310. It is all right for you to make the——

A. I do not know of anything outside of phosphorus that was used.

XQ. 311. At 1909?

A. At 1909.

XQ. 312. You do not know that magnesium was used?

A. Not in lamp practice.

XQ. 313. Or calcium?

A. No.

XQ. 314. Did not Soddy prior to 1909 mention both magnesium and calcium?

A. Yes, for his pump.

XQ. 315. But you did not consider that to be a chemical evacuation?

A. Yes, it is, Mr. Darby.

XQ. 316. That is just what I asked you.

A. Then I missed your question.

XQ. 317. Very well, I will repeat it. My question was this: The Merritt patent states that some one of the well known agents suitable for chemical exhaustion could be used. Now, my question is, what chemical agents were known? That is, what agents suitable for chemical exhaustion besides red phosphorus were known at the date of the Merritt patent?

A. Well, I have answered with respect to lamp practice that I think red phosphorus—

XQ. 318. My question is not confined to lamp practice.

A. And to answer that with respect to what chemical exhaustion materials had been proposed to be to 1909, I would have to go through the publications chronologically, which I have not done.

XQ. 318a. Can not you do it from recollection?

A. I can agree with you that Soddy proposes both calcium and magnesium before 1909.

XQ. 319. And potassium and sodium?

A. They were referred to in one of these patents as having produced displacing gases, as I recall it.

XQ. 320. All right. Now, will you please refer to the Clough patent No. 1,246,054?

A. I might add that the Dwyer patent is the one which I am speaking of. Yes, I have the Clough patent.

XQ. 321. It is a fact, is it not, that the magnesium calcium or this material that is employed in that patent, is employed for the purpose of getting out all oxygen-containing gases, or oxygen out of the oxygen-containing gases?

A. I was under the impression that that was not stated, but that the purpose was given as to reduce the voltage drop by using a metal highly reactive chemically to gases other than the so-called rare or monatomic gases. For instance, page 1, lines 48 to 50. Perhaps you can find a reference to a direct effect on oxygen. I do not remember it.

XQ. 322. In other words, the patent is even broader than my statement, is that correct?

A. Yes. It makes no specific reference to the oxygen-bearing gases, so far as I find.

XQ. 323. And the purpose of employing magnesium calcium or the like, so as to get out all gases other than the so-called rare or monatomic gases, is that correct?

A. It does not say that. It says that the purpose is to reduce the arc drop, and he uses an anode of a metal highly reactive to the others.

XQ. 324. What was the purpose of using that?

A. I think it was to attack the gases and to reduce the arc drop.

XQ. 325. Attack the gases in what way, chemically combining with them?

A. I think it would do that, whether it was recognized by Clough or not, yes.

XQ. 326. And you know that calcium magnesium of course would take up any oxygen?

A. Yes, in a hot state.

XQ. 327. Now, I think this is clear, but I want to make sure that it is. As I understand your testimony, the magnesium of patent No. 4, not only acts as a getter, but it also acts as a keeper, is that correct?

A. Yes. If you mean what I do. That is, that the flash of magnesium in the tube, whether it be the electrical flash of the heated coil type shown in the patent, or the heating produced electrically by the induction furnace, that is used in practice, gives a hot, highly active vapor which operates as Soddy pointed out, to improve the vacuum, to get a higher vacuum or a lower pressure. Then after that, which is a factory process, the film on the wall acts in accordance with this Langmuir patent to keep the partial pressure of oxygen down to the desired low value.

XQ. 328. And it does that by the film of magnesium on the wall, as it combines with any gas that is liberated, and takes out so to speak, any oxygen therein contained; is that correct?

A. It may not be a direct chemical combination, but we do know that oxygen and water vapor are held to the surface of the magnesium film, and that the large area of the film exposed by the tube, as compared with the smaller area of the tungsten filament is such that the probability of collision of the oxidizing gas with the wall is very much greater than its probability of collision with the filament. Therefore, that even though the magnesium is not so active chemically as thorium, it acts to protect the filament surface.

XQ. 329. I think you had stated all that in your direct examination. I was trying to boil it down into a very brief statement, if I can get you to agree with me, that the magnesium on the inner surface of the tube performs the function of taking up any oxygen or gas evolved after the tube is put in use; is that correct?

A. It is not correct. It does as to the first part of your statement prevent the oxidation of a filament. The first part is correct.

XQ. 330. Prevent the oxidation of the filament?

A. Yes.

XQ. 331. It likewise takes up any water vapor that is present in the tube afterwards, is that correct?

A. Yes. Of course, it also seals on anything that there might be in the glass that is another feature.

XQ. 332. Seals on?

A. Yes, it covers and pastes over any molecules that might be left on the inside of the wall.

XQ. 332a. That is inherent to flashing the magnesium, is it not?

A. Yes, and to the deposition. It would also be done by the tungsten of the second patent.

XQ. 333. Now you understand that the magnesium is employed in patent No. 4 in suit after the initial pumping on the pump; is that correct? In other words, its function is not to take out all the gases or obtain the initial vacuum, but it is to take out the last traces of the gases after the pump has performed its function?

A. Yes. Its real purpose is to take out the oxygen bearing gas to the extent necessary to protect the thoria, and it is flashed after a good deal of pumping has been done.

XQ. 334. And patents No. 2, 3 and 4, all describe the degree of evacuation, if not in words, but in the sense that the degree of evacuation is desired—the degree of evacuation that is desired is so high that there is practically no ionizable gas remaining; is that right?

A. Well, that is a different feature, of course, from what we have been speaking of.

XQ. 335. I understand it is different.

A. It is true that first the oxidizing partial gas pressure must be exceedingly low, and second, that the other gas pressures which may give rise to bombardment, must be below a pressure at which substantial ionization takes place.

XQ. 336. In other words, maybe we can find a common ground in this expression—the operation of all of the patents in suit depends upon pure electron flow as distinguished from gas ionization; that is correct, is it not?

A. That is generally correct except that I hope you are not using "pure" in the sense of 100 per cent. because——

XQ. 337. I do not think anybody has in this trial, Mr. Hogan?

A. All right. As long as you are not doing that, I am satisfied.

XQ. 338. Then all four patents operate on pure electron flow, and I think you will likewise agree with me that you could not get pure electron flow if there is substantial amounts of gas left in the tube?

A. Yes, and if you operate above ionization.

XQ. 339. Yes. Now, with respect to the magnesium method, the magnesium pump, I think you called it, or a calcium pump, can you by means of a calcium pump alone get a sufficiently high vacuum to enable the operation of the three-electrode tube, let us say, or a two-electrode tube, by pure electron flow, with voltages substantially above ionization?

A. No, I think not.

XQ. 340. Then you would have to use something in addition to that. You referred to the practice that is at the present time being employed by flashing the magnesium while it is still on the pump. The fact that the pump is still connected to the tube when the magnesium is flashed, does not, of course, prevent the magnesium from hitting the surface of the tube so as to form that film?

A. That is correct.

XQ. 341. And in the practice that you are familiar with is the pump still in operation while the magnesium is flashed?

A. I think so.

XQ. 342. Then let us refer to the White patent, and I call your attention to page 3 of the White patent, line 40. Before I ask you that question, let me ask you this: You understand, do you not, that the White patent describes a tube which is initially evacuated to such a degree that current conduction can take place from cathode to anode by means of specially pure electron discharge as distinguished from gas ionization?

A. Yes.

XQ. 343. All right. Let me call your attention to page 3, line 40, where the statement is contained:

> "The evacuation of the tube is carried out by the most approved methods of incandescent lamp exhaust, and the last traces of gas are removed by either a Gaede molecular pump or by some chemical evacuating means, such as the use of vaporized calcium or magnesium."

You do not understand from that statement, do you, that White meant in his patent that he could use a molecular pump?

A. Why not?

XQ. 343a. You do mean that?

A. I think it is perfectly possible, yes.

XQ. 344. And I understood you to say a minute ago that you could not obtain a sufficient high degree vacuum with a magnesium pump so that you could get the flow?

A. Your question said magnesium pump alone.

XQ. 345. Yes.

A. That is correct.

XQ. 346. Then you consider this as being in addition to the Gaede molecular pump, that is the mechanism used in addition to the Gaede molecular pump?

A. No, I think the last traces are removed by either a Gaede molecular pump or by some chemical evacuation means following the pre-treatment described in the first part of that paragraph, and the best and most approved method of incandescent lamp exhaust referred to.

XQ. 347. And what pumps do you know of that will perform that function other than the Gaede molecular pump?

A. Perform what function?

XQ. 348. Perform the function of enabling one to get a sufficient high degree of vacuum so that you can operate these devices by reason of the pure electron flow as distinguished from gas ionization?

A. Why, even for the ordinary tube, a Toepler pump, and I think a Sprengel pump, if the mercury is kept out with solid carbon dioxide or liquid air, it will give you amply low enough pressure for the ordinary purpose.

XQ. 349. Do you know Mr. Saul Dushman?

A. Yes.

XQ. 349a. He is one of the Research Engineers of the General Electric Company, is he not?

A. Yes, that is correct.

XQ. 350. He attended part at least of this trial?

A. I think so.

XQ. 351. And he is also an author of the book entitled "High Vacuum," is he not?

A. That is correct.

XQ. 352. You have read that book?

A. No. I have used it as a reference book but I have never read it from cover to cover.

XQ. 353. Mr. Dushman states in this book on page 134:

> "In considering absorption of charcoal at low temperature, immediately below a table:—
>
> "That is, at a pressure of 0.01 bar (which is a maximum pressure for the efficient operation of hot cathode high vacuum devices) one gram of charcoal (such as used by Claude) would clean up about 130 centimeters of hydrogen or 18,000 centimeters of nitrogen from a pressure of one bar down to 0.01 bar."

First, let me ask you this: 0.01 bar is equal to .0075 microns, is that correct?

A. Approximately.

XQ. 354. About seven and a half thousandths of a micron. Now, do you agree with Mr. Dushman's statement that seven and a half thousandths micron is a maximum pressure for the effiecient operation of a hot cathode high vacuum device?

A. It may have been perfectly correct——

XQ. 355. Do you agree with that?

A. Not in general, no.

XQ. 356. You do not agree with that in general? What did you start to say?

A. I started to say that it might be correct for a device which he had in mind, but I do not know of any limiting pressure which will define the point at which the substantial ionization occurs in a wide class of devices.

XQ. 357. Then it is your opinion that Mr. Dushman must have had some particular device in mind when he made that statement?

A. I think that is likely. I know the effect is that the pressure at which harmful ionization begins, depends very largely on the geometry of the device, that is, on the actual design.

XQ. 358. Can you tell me what is the material? What do you mean when you say that the material can be "sublimed"?

A. Can be "sublimed," I think that means that it gives a vapor off about apparent boiling, that one can see in the case of water.

XQ. 359. In other words, magnesium is a vapor which can be sublimed, is it not?

A. I do not know. It was a vapor pressure.

XQ. 360. Has calcium?

A. Yes, they all have vapor pressures, without seeing them boil, if that is what you mean by "sublimed."

XQ. 361. Yes, magnesium, potassium and sodium are all metals which can be sublimed?

A. They are all metals which have vapor pressure from a solid state.

XQ. 362-63. And do not have to be boiled, according to your definition; do you mean that that statement found on page 204 of Dushman, and I may explain that this appears in a shape relating to "chemical and electro-chemical clean-up of gas at low pressure."

> "As mentioned by Dr. Whitney, arsenic, sulphur and iodine act in a similar manner to phosphorus in cleaning up gas in incandescent lamps. In fact any substance that can be readily sublimed acts in the same manner."

Do you agree with that statement?

A. No, I do not know the boundary conditions well enough to accept that.

XQ. 364. Then in consideration of this clean-up Mr. Dushman states on page 201:

> "In general, over 90 per cent. of the residual gas is cleaned up in a lamp during the blue glow period."

Do you agree with that?

A. That agrees with my understanding, if you mean the clean-up of lamp manufacture, where the use of phosphorus, for instance, is accompanied by blue glow?

XQ. 365-66. And then the statement continues:

> "and the rate of clean-up during this time is much more rapid than that obtained subsequently. The final pressure attained on flashing varies from 0.01 to 0.001 × 10 = 3 mm. of mercury."

That means from—just translate that to microns, will you?

A. If I heard you, it is .01 to .001 microns.

XQ. 367. In other words, from one-hundredth to one-thousandths of a micron, is that correct?

A. Yes. That is, those are the figures you have given me. I have forgotten the context.

XQ. 368. "This final pressure obtained by flashing varies from .01 to .001"?

A. I do not know as to the fact, but I do know that these pressures correspond to these number of microns.

XQ. 369. Do you agree with that statement?

A. I say I do not know. I do not know what is attained on the flash. My impression was that it was not as low as that.

XQ. 370. Was not as low as that? You mean that you would not get as low as one-thousandths of a micron by flashing?

A. Not as the result of a phosphorus flash with blue glow in the ordinary lamp.

Mr. Darby: That is all.

The Court: Mr. Richmond, have you some cross-examination?

Mr. Richmond: Not at this stage.

The Court: Very well.

Mr. Davis: With your Honor's permission, I will continue the direct examination of the witness on other aspects of the case than those touched by Mr. Edmonds.

The Court: Very well.

Direct Examination (Continued).

By Mr. Davis:

Q. 371. Mr. Hogan, what are the practical devices or tubes of the prior art which have been referred to in this record? I merely want a list or enumeration of them.

A. It includes the Fleming valve——

Mr. Richmond: I object to the question. It seems to me it calls for a summary.

The Court: You can embody that in your question, if you want to, to the witness, to go on from that, and I think it would be very nearly proper, as I understand it, if you ask the witness to summarize for you.

Mr. Davis: If your Honor please, what I am trying to get at is to separate and for separate consideration, an actual working device from the devices described.

The Court: I still am under the impression that Mr. Richmond's objection is good and that you may make that assumption in your question, and deal with it on that basis, rather than ask the witness to summarize testimony.

Q. 372-73. On the assumption, Mr. Hogan, that the practical devices of the prior art referred to in this record are the Fleming valve, the DeForest audion, the gas X-ray tube, the mercury vapor tube and the incandescent lamp, I want to ask you one or two questions, the first being—is an incandescent lamp an electron discharge device?

A. No. The operation at the same time might conceivably be accompanied by some electron discharge across the filament terminals, but that is of no value; in fact, could only do harm, so I would not classify them among the electron discharge device group.

Q. 374. Then if we are ignoring incandescent lamps, and if we adhere to the assumption which I made with regard to the Fleming valve, the DeForest audion, the gas X-ray tube, and mercury vapor tube, and regard them as practical devices, will you please tell me what were the orders of magnitude of pressure in those four devices as they were used prior to 1912?

Mr. Darby: If your Honor please, I have to make an objection to this line of examination, on the ground that I think that the witness in answering the question would have to be going into the judicial field rather than the expert field.

The Court: The objection is overruled.

A. The pressure of the Fleming valve was that of the ordinary incandescent lamp, something of the order of ten microns. Possibly worse, possibly better, depending upon the lamp with which it is compared. The DeForest audions that I have measured showed vacua of about the same degree or pressures a little higher. That is something of the order of five to ten microns.

Q. 375. Excuse me, you said pressures a little higher?

A. Yes, pressures higher in some cases. I have gotten considerably higher pressures than ten microns in DeForest audions.

The Witness: X-ray tubes of the old-fashioned type, on the other hand, I have never measured, but I understand that the pressures there run from 3 to 10 microns.

THE COURT: No. Why should not that be stricken out, Mr. Davis; why should we have his understanding? It might be based on other things.

MR. DAVIS: I am perfectly willing, if your Honor please, to strike it out. I will ask another question, which I think will develop his answer.

THE COURT: The latter part of his answer will be stricken out.

Q. 375a. Let us first deal with the mercury vapor tubes; what was the order of pressure there?

A. Centimeters, that is to say, very high pressures.

Q. 375b. Now, the gas X-ray tube. It has been testified in this case as a fact, and I think by witness of both sides, that as the vacuum improvements in the old-fashioned X-ray tube developed, there came a time when no more current would pass through it, and then the tube became inoperative from the standpoint of the art, as it existed at that time. Does that fact enable you as an expert to state what the vacuum was in a working X-ray tube before that phenomenon occurred, if so, please state it?

A. That makes it perfectly possible to state that the vacuum before the discharge stopped, that is to say, as the pressure was being reduced, was something of the order of two to ten microns or thereabouts. I know from measurements that have been made by others and that have been published, that the pressure of the residual atmospheric gas has been measured over the operating range of hardness, and is from about 4 microns to about 13 microns in the old-fashioned X-ray tube. The hardest rays possible being produced at 3.7 microns. Now, that is clear confirmation of the view that if the pressure were reduced a little lower than 3.7 microns, no more X-rays would be produced but the tube would stop, because those two things go along hand in hand. For those measurements I am referring to a paper by Lindeman in the *Physikalische Zeitschrift*, 1912, February, pages 104 to 106.

Q. 376. Will you please discuss now the degree of vacuum necessary to the accomplishment of the purposes set forth in the first patent in suit?

A. That vacuum is not a fixed thing. It depends upon the spacing and the form of the electrodes and on the voltage to be used with the tube and the use of the tube. In general, it is such a vacuum as will give what we have been calling substantially pure electron discharge free from harmful effects of positive ionization and the pressure that will give that desired result will be different for different types of tubes, and possibly even for different operations of the same tube.

Q. 377. How can such a vacuum be obtained and maintained in a useful working tube?

A. If one should take, for instance, a prior art tube such as a Fleming or a DeForest tube or I suppose even an X-ray tube and convert that or try to convert that into a Langmuir tube of the patent it would require a preparation and evacuation of the tube and its electrodes in a very different way from that which was practiced in the ordinary manufacture of those old tubes.

It would require a final pressure for those geometries of a different order of magnitude and one that could only be had by combined and exaggerated, so to speak, use of all the preparation and evacuation steps that were known.

For instance, Dr. Langmuir's December, 1913, *Physical Review* paper at page 32 of the reprint, which I have here, gives the normal conditions and treatments that he would use for making one of these tubes. He says, first, speaking generally, that there must be an extremely high vacuum, and he refers to a pressure below one-tenth of a micron. At page 20 of the paper he gives a specific instance of .07 microns pressure. He says in this section No. 1, and in the two succeeding sections what one must do to get high vacua and the steps that he outlines are the elimination of all stop-cocks and wax joints; the heating of all the glass to 360 degrees C. for an hour or more; the avoidance of the old-fashioned anode treatment by an ordinary glow discharge. That I think it has been explained to your Honor that that results in releasing gas in the tube and sticking it into the walls so that it may make more trouble later on.

Mr. Richmond: I want to object to reviewing that Langmuir paper with this witness. It seems to me——

The Court: I will hear you, Mr. Davis.

Mr. Davis: I have asked the witness how this vacuum can be obtained so that it could be maintained in the tube. If he chooses to summarize it from that paper, I do not see why he should not.

The Court: I see no occasion for it. He is going far afield. The answer is stricken out.

Mr. Davis: Only the part where he begins talking about the paper.

The Court: Yes.

By Mr. Davis:

Q. 378. Then quite independent from Dr. Langmuir's paper, will you state what these conditions are which have to be fulfilled?

A. You would like me to itemize the desirable things that should be done to produce a tube of this sort?

Q. 379. If you please.

A. Elimination of the stop-cocks, and the wax joints of the old-fashioned exhaust system; heating of the glass of the vessel being evacuated at a high temperature, nearly the softening point of glass for a reasonable time; avoidance of the anode treatment by high voltages in the ordinary glow discharge; heating of the anodes or other normal cold electrodes to high temperature, as for example 2500 degrees, for a reasonably long time, as for example, ten minutes while they are in the apparatus being evacuated; heating of those electrodes, if they are of wire, by passing a current through them or if they are of a serially connected strip in the same way, or if they are not so formed, but in plate form, by bombardment at high voltages (possibly several thousand volts) and high currents of the order of 100 milliamperes or thereabouts, enough in any event to heat them to a bright red or white heat while they are on the pump. The cleaning of the filaments by heating them, and of course, the elimination of mercury or any other vapors by the use of a liquid air trap or carbon dioxide in a solid form or some equivalent.

Q. 380. In your answer, have you or have you not assumed the presence of such a material as magnesium on the inside of the bulb?

A. I have not assumed the presence of any such material.

Q. 381. Now, making the assumption that such material is present, does that modify these requirements to any extent?

A. Yes. If one is operating at relatively low volttages and using the tube cold or practically cold it is not necessary to go to the extremes of treatment in order to produce a satisfactorily low pressure that will remain satisfactorily low when magnesium is used both as a getter and keeper as it would be if there was no such chemical treatment and no such keeper available.

Q. 382. Do you regard the disclosure of the Langmuir patent as a matter of getting a little better vacuum than existed in the three-electrode devices, such for instance as the DeForest detector tube?

Mr. Darby: I object to that.

The Court: The witness may answer the question.

(Q. 382 repeated by the stenographer.)

A. The point there is that a change in pressure from two microns down to five-hundredths of a micron just assuming values for the purpose of the discussion, is of course a small change relative to atmospheric pressure. We would notice no such change in pressure as that, no such differential pressure as that in the room. On the other hand, it represents a change in pressure to something that is of an entirely different order, a factor of forty to one or something like that and of course such a range of pressure change as that as a matter of ratios would be more than any of us could stand. I mean that absolutely, in terms of pressure, the change needed to make a DeForest audion into a Langmuir tube, provided the electrodes have been treated and everything else was done that was necessary, would be small. The pressures themselves are small. But as a matter of what is really done, comparison of the one pressure to the other pressure in terms of their relative size, the change is tremendous and to an entirely different order, and of course I say that still with reference to the fact that absolute values must be defined only with respect to some particular tube and not in general.

Q. 383. Will you please discuss the practical results which that difference produces?

A. The result of making a tube with the treatments for the attainment and maintenance of the practically non-ionizing condition that we have been talking about, the results of that are dependent mainly on the two features that I have referred to, first, that the Langmuir tube is uniform in its operation, day after day and that it therefore can be standardized for a definite purpose; secondly, that the Langmuir tube is capable of either amplifying or rectifying or controlling large amounts of electric power, a matter of kilowatts or thousands of watts as against the thousandth parts of watts in the old tubes.

With regard to the uniformity of operation that makes possible simplicity. There is no necessary adjustment of the plate battery voltage and even the adjustment of the filament current is not critical; and because of that the operation of groups of tubes, for instance, in telephone repeaters or in multi-tube radio receivers, becomes practical. If one had to make individual adjustments of filament and plate current and voltage on each tube of a multiple tube radio receiving set, I venture to say that nobody, even the most skilled manipulator, would be able to run a superheterodyne with eight tubes, for instance.

Another consequence of this uniformity is that replacement of the tubes without changing the apparatus becomes possible. That is particularly important in telephone repeaters and in radio devices both of the receiving and transmitting type. One wants to know that he can replace a burned-out tube with a new tube without having to make substantial changes in the apparatus.

The third thing that arises from uniformity is the possibility of effective use of the tube in complicated circuits. The Langmuir tube does not vary as to its constants while it is in use; and because of that radio sets, for example, can be designed for high efficiency and kept constant at the high efficiency point because the tube does not change. In telephone repeaters, for instance, one can balance the line closely and keep it from singing by reason of the constancy of the tube.

The old tubes would not permit such adjustments in either of those cases because of their variability.

The fourth point flowing from the uniformity of operation is that special apparatus can be now made for special services, because the tube constants stay fixed. For example, special types of amplifiers are made which have special constants and the X-ray tube is a special tube which has a special set of constants. Neither of those things could be done if the uniform operation were not available to us.

With respect to the second point, that is power handling capacity, for telephone repeaters it was desirable to have more power than milliwatts, thousandths of a watt, because the quality depends upon the greater amplifying power as also does the intensity to give satisfactory service. For example, a present-day use of telephone amplifiers is in conjunction with the public address system which is used when a speaker wishes to talk to a large crowd of people. The power output of such a tube is really tremendous compared with the tubes used on the telephone lines and such power handling capacity could not be thought of in connection with the old art tubes.

For radio amplifiers, the amplifiers used in connection with radio receiving sets, the increased power handling capacity is very important. Every one who is well informed knows that the quality as well as the intensity of the response from a loud speaker depends not merely upon the loud speaker itself and upon the broadcasting station, but also on the power-handling capacity of the amplifying tubes in the receiving set.

It is very striking to change a small tube, and replace it by a good power-handling tube in a receiver and see what improvement in the quality comes from that change alone.

For oscillators in radio transmitting stations, the ordinary powers used are anywhere from fifty watts to fifty or more kilowatts. Twenty kilowatt single tubes are commercial tubes now. For modulators in radio transmitters, for tubes used to vary the intensity of the constantly flowing stream of electro-magnetic waves in accordance with voice outline, tubes of the same order of power capacity are needed and that again comes from the high power limit of those devices; and still further and last of all in rectifiers for industrial purposes it is necessary, as for instance in smoke precipitators or other places where industrial amounts of power are used, it is necessary to have such tubes to handle such amounts of power and that again flows from the feature I have discused.

Q. 384. Will you now discuss the prior art discussed by Professor Chaffee in its relation to the first patent in suit and in doing so, when you come to the discussion of the Fleming publications and the Fleming patent, please refer to Mr. Waterman's deposition in the old suit Marconi against DeForest which is mentioned on pages 1486 to 1489 of the record in the present suit?

A. I have already discussed a number of the references cited by Dr. Chaffee in connection with their application to the second, third and fourth patents but I will go ahead, taking the exhibits up in the order in which they were introduced here and when I come to those which I have already treated, I will refer to that fact and make any other comment which might be helpful in connection with their relation to the first patent.

The first exhibit is No. 2, the Dewar article of 1875. That describes simply a chemical pump, using heated charcoal, the vessel first being heated and the charcoal being allowed to cool so that it will condense a small residue of gas, and it can produce nothing of the order of vacuum required today. I think Dr. Chaffee agreed that liquid air was not available in 1875, at the time this article was published.

The next exhibit is Exhibit 3, an article by Scheele and Heuse published in the *Zeitschrift* for February, 1909, pages 45 to 50. That particular article is one of which I have no translation. I have had it read in German and understand that the evacuation mentioned was that of a device which had no electrodes, that a vacuum of approximately seven one-thousandths microns was measured with a McLeod gauge in this tube using charcoal and liquid air but that the McLeod gauge under those circumstances would not show any vapors which might have escaped into it.

I do not know whether the charcoal and liquid air was sufficient to condense all the vapors or not. I do not know how it was used. In any event, there is no mention of sealing off from the pump or from the cooling agent in the article except with relation to stopcocks; and of course we know that if a device, even pumped down to one one-hundredth of a micron, is sealed off from a pump on which it shows that pressure, by the ordinary methods of lamp sealing off, the gases given off will increase so that the final pressure after sealing off will be of the order of one or two microns.

This article has no mention of maintaining a vacuum nor of keeping it longer than it stayed on the pump. I should like to reserve any further comment on the article until I get a translation. That is my understanding from what has been given to me. In other words, everything that I have said is on the assumption that the oral translation is correct.

The same comments as to translation apply to Exhibit 4, Bessel-Hagen. We have no translation of that in written form but I have gone through the article with Dr. Dushman and understand that here again the device was not sealed off but the pressures were measured with the pump running. When an electrical discharge was sent through a pair of electrodes on the little tube at the right of Figure 8, the gas pressure increased from nine microns to seventeen microns and then again to thirteen microns upon the application of the current. There is no reference to heating the electrodes. And while a measured or recorded pressure of 8/1000ths of a micron is referred to it is very difficult if not impossible to read such pressures accurately and it is impossible to maintain them after a seal-off on the ordinary lamp basis. This particular paper was referred to in the Interference record by Dr. Langmuir at page 1488 and the Scheele and Heuse paper Exhibit 3 here, was treated by him at the same place.

Exhibit 5 in this case is Edison Patent 411,019 of 1889. It shows the heating of a lamp globe first in an oven and then through the exhaust it is warmed by a lamp applied to a chamber. It shows the use of phosphoric anhydride, P_2O_5. The tube is put on a Sprengel pump with rubber bands. While it shows a recognition of the desirability of removing enough water vapor from the tube to prevent the burn-out of the carbon lamp filaments, it certainly has no suggestion that the methods used with a thermionic tube would give a low pressure.

There were no anodes in the lamp and there was no suggestion of glowing the lamp filament, so that those reservoirs of gas would not have been emptied following this process.

The next is Exhibit 6, the Malignani patent, to which I have referred in the record at page 1568. This is a publication descriptive of a method which will attain a lamp vacuum of one or two microns up to perhaps ten microns, but of course it would require much better pressures than that except perhaps in tubes of exceedingly special design to operate without ionization at voltages that were above the ionizing potential.

Certainly no such pressures would be useful in a good tube, because it was the pressure used in the old Fleming valves.

Exhibit 7 is the Dwyer Patent 596,654. That also I commented on in connection with the last three patents in suit here, my discussion being at page 1570 of the typewritten record; and here again we have something which is no more than a lamp vacuum produced in a carbon lamp.

Exhibit 8 is an article by Duncan which was published in the *American Electrician* for May, 1896, pages 8 and 9. This refers to experiments on Crooke's tubes. The author shows some photographs of Crooke's tubes with luminous discharges and gives a large part of his paper to a discussion of the electrode connections which will prevent the discharges from crossing and gives a discharge that is better.

He showed an increase in the vacuum of X-ray tubes and lamps in their ordinary ~~use and~~ he believed that might be due to a combination of the residual air with vaporized carbon, as he states in column 1 of the article. I can stop here as well as any other place.

The Court: 2.15.

AFTER RECESS.

By Mr. Davis:

Q. 385. Unless there is objection to Mr. Hogan's testifying for the sake of saving a little space in the record, I am going to ask you simply to tell us what the investigations were which were referred to in this *Physikalische Zeitschrift* paper of 1912, which you referred to this morning, and you can read just that first part of the table which gives the results we are interested in.

A. This was a set of results of the measurements of hardness of rays produced by an ordinary gaseous X-ray tube when the vacuum or pressure within the tube was changed by measured amounts. To measure the hardness, the so-called Wehnelt scale was used, which I understand is the arbitrary set of numbers, having to do with the penetrating power of the rays, and the harder the ray, the higher the number; and the pressure was measured in microns or thousandths of millimeters. The table at the upper left-hand corner of page 105, gives the results for atmospheric residual air, and the first two columns are headed respectively "Pressure" ("McLeod Pressure") in the equivalent of microns, and second, "Hardness by the Wehnelt Gauge," and the numbers in the two columns corresponding to each other:

Pressure	*Hardness*
13.6	2.7
9.7	3.2

Perhaps the best way would be to let Mr. Smart typewrite this instead of my reading it.

Pressure	*Hardness*
13.6	2.7
9.7	3.2
8.0	4.2
6.6	4.9
6.8	5.5
6.8	5.7
5.7	6.5
5.2	7.8
5.0	8.0
3.7	10.3

Q. 386. If you will please continue your answer—

The Witness: Continuing then with Exhibit 8 the Duncan article, he suggests the same explanation. Vaporized materials might explain the clean-up in Crookes or X-ray tubes. He then talks about lamp makers, not being able to make satisfactory Crookes tubes in general, and that to make a good X-ray tube, lamp practice must be improved. That is, of course, exactly what one would expect if the simple procedure that is satisfactory for a lamp were applied to a tube having the large electrodes characteristic of the X-ray tube.

Not only would the gas be too high for an X-ray tube performance, that is above 10 or 12 or 15 microns, but probably a great deal higher, unless the precautions that Duncan suggests are followed. He says that he has gotten good X-ray tubes from lamp makers, and he says that he was simply trying to attain in these tubes a good X-ray vacuum, which, for high penetration, as I have shown, might be as much as 3 microns instead of a poor carbon lamp vacuum which might be as high as 10 microns, and would be considerably higher in an X-ray tube made according to simple lamp practice.

In his satisfactory tubes of the Crookes types he got a visible cathode ray discharge showing the intense ionization, and whatever vacuum he did get was of course not maintained, it being the essence of both the Crookes and the X-ray forms of tubes that the heating of the cathode by ion bombardment is essential, and of course there was no approach to the vacuum of the first patent.

The next exhibit is No. 9, the Dewar article, from the proceedings of the Royal Society, 1898, pages 231 to 238, which refers to the use of liquid hydrogen to produce vacuum. He used both electrodeless and sparking tubes for examination of the spectra in the glow discharge under various conditions. Apparently the cooled portions were never sealed off, and this was condensation of condensible gases or freezing of the gases in liquid hydrogen and not absorption of the gases by charcoal.

On page 234 of the article he got what he considered evidence of pressures below one one-millionth atmosphere, which corresponds to six-tenths of a micron, and in that connection, Dr. Chaffee on page 511, I think computed that is six one-thousandths of a micron, but he must have in mind six one-thousandths of a millimeter, or six-tenths of a micron. This suggestion of a freezing process would not maintain even such a vacuum after the liquid hydrogen had been removed. The form of the tube is shown on the sketches on page 234 and the article is described by Dr. Langmuir in the Interference record on page 1488.

The next Exhibit is No. 10, which is an article by Lenard appearing in the *Annalen der Physik*, 1900, pages 359 to 374. It has to do with experiments with photo-electric discharge on tubes with a quartz window, sealed on, and of course, exceedingly small currents, something of the order of billionths of an ampere, wherein there would be no space charge. He sealed the tube and passed sparks through it, and absorbed some of the moisture in the tube with pentoxide and at least once condensed mercury from his pump with solid carbon dioxide, the soda water treatment, so to speak.

Apparently he left the apparatus on the pump all the time. He said that the condensation produced no change in the discharge, so evidently that was not essential for his purposes. He may have had a harder vacuum, somewhat harder than the operating X-ray tube vacua, which go down to 3 microns or thereabouts, but he measured it by the point where the ionized discharge in the tube stopped, so that it could not have been very much below that, if any.

The whole tube is outside of the range of the thermionic vacuum tubes of the sort we use and get from the Langmuir patent. It had no filament, there was no substantial heating of electrodes in the preparation or in the use, and his process would be entirely inadequate to prepare a Langmuir tube. In the Interference record, both Millikan and Richardson referred to this as a pure electron discharge; that is to say, a photo-electric pure electron discharge, and of course there is no doubt that below ionization voltages, and in the saturation range, of photo-electric effects, even at the high pressures of these experiments, the discharge was substantially of the pure electron type, but that has nothing whatever to do with the pure electron discharges at ionizing voltages, and under space charge conditions.

Now, Langmuir discusses this paper in the Interference record at page 1465. I may not have mentioned that the diagram of the Lenard apparatus is shown as his Figure 1 on page 361 of the original, the sealed quartz glass window appearing below a portion of the plate.

Now, Exhibit 11 is the article "A Resume of Incandescent Electric Lamp Exhausting," by Doane, printed in the *Electrical World and Engineer* for May 21, 1904.

I discussed this article in connection with the last three patents in suit at page 2607, and I think the comments there apply here. There was no recognition of bombardment between the filament legs, although that was referred to by Dr. Chaffee at page 542. The blue glow that is referred to we have seen may produce more gas than it cleans up, if the tube has gas or partly prepared tube walls, or if there is gas in the filament joints or in the electrodes, and those Doane's tubes (being lamps) had no electrodes other than their filaments, and there is no suggestion of attainment in them of any of the lower pressures, than the carbon lamp vacuum which I think has been accepted by all of us to be somewhere between two and ten microns of pressure, and incidentally there was no heating on the pump in that article, so far as I recollect.

Now, Exhibit No. 12, is U. S. Patent No. 946,068, to Von Recklinghausen, and that also I discussed in connection with the last three patents, on page 1574 of the transcript. Dr. Chaffee classified it only under the vaporizable reagent and the alkali earth metal groups at the end of his deposition, where he classified all the references according to their disclosures, so I believe it is cited only as to the last three patents, but I think it is perfectly clear that a mercury device like Von Recklinghausen's would be a device that depends for its operation upon ionization, and that no operation free of ions could be produced under the conditions in such a mercury lamp.

Exhibit No. 13 is U. S. Patent to Merritt, No. 909,811. That also is a lamp patent which I discussed in connection with the last three patents in suit on page 1576 of the record herein. Dr. Chaffee referred to this as showing baking walls of the tube and heating the electrodes of a tube; but so far as I can tell from the patent, the bulb was oven-heated prior to the exhaust—there is a reference to that—but there is no reference to electrode heating other than the filament. I think by this process he would attain a lamp vacuum at the time of seal off of probably a few microns, but nothing more.

Now, Exhibits 14, 15 and 16 are respectively the Fleming 1905 article, or paper before the Royal Society, published in the proceedings beginning at page 476. The United States Patent No. 803,684, which is on the device described in the Royal Society of London paper, and the popular article in the *Scientific American Supplement* for January 20, 1906, which is a reprint, word for word, I believe, of the same article published in *Technics* for April, 1908, beginning at page 316, and which is, as I think Dr. Chaffee agreed with me, a popular resume of the disclosures and work described in the Royal Society of London paper. Therefore, I will treat all three of these together.

The disclosure, the showing, is of the well-known Fleming valve, and that attained its practical use, and I think its only practical use, as a radio detector. As it was used, and as I have used it, and without exception, so far as I have been able to learn, by direct inquiry from those who have used it, the filament voltage was from four to twelve volts. That is to say, different tubes had different filament voltages of from four to twelve, and they were never used with any battery other than the filament battery. Therefore, if the anode is connected to the positive terminal, the voltage with respect to the negative end of the filament, cannot be more than twelve volts maximum. If it is connected to a potentiometer, as was common in the use of the device, the potential on the grid can be varied from this value of plus 12, corresponding to the most positive point of the filament down to the negative end of the filament, which gives a zero potential with respect to that, since that is from where it is measured.

In other words, the anode I think was never charged to a voltage higher than the ionization potential of the residual gas, and, as the result of that, disturbing effects of gas on the discharge would not appear even though the device had pressures of the usual carbon lamps, say from ten down to two microns. If the pressure were very much higher than that, say 100 microns, the filament would be likely to suffer, and also I think there would be some interference with the passage of electrons, even below the ionization voltage.

Simply because of the obstruction, practically a mechanical obstruction produced by the inert gas molecules that would be in the way, even though no ions. Fleming recommended the incandescent lamp pressure, and there would be no advantage in going below this, because he operated below ionization potentials. In order to get pressures of that order, he found it helpful to heat his metals within the tubes to some extent. For instance, he suggests an external resistance coil, used to heat the cylinder contained inside the tube, and that would be helpful, I believe, to get that kind of a vacuum.

Mr. Darby: May it please your Honor, I move to strike that out because the witness is paraphrasing the Fleming article, rather than pointing out what the Fleming article states. I move to have his answer stricken out.

The Court; That portion of it, Mr. Davis.

Mr. Davis: That last few lines, is all I understand the objection is to, and I will ask him to continue his answer without paraphrasing.

The Court: That portion will be stricken out.

The Witness: Suppose we refer to the patent and read, page 1, lines 100 to 105 (reading):

> "The filament b can be conveniently heated by passing a current through it, while the cylinder c can be heated by surrounding the bulb a with a resistance coil through which a current is passed, the whole being inclosed in a box lined with asbestos or the like."

That has to do with the feature which I tried to state more briefly by summarizing. The curves that he gives——.

Q. 387. Just a minute, Mr. Hogan. I would like to have you state whether if you have not already done so, I am not quite sure how far back this order to strike out goes—whether or not that was an effective means of cleaning up the plate?

A. Why, no. It would help to get the sort of vacuum that Fleming needed. This was an incandescent lamp vacuum, and it is very probable that he could not have gotten down to even ten microns unless he had done something of that kind. It is not anywhere near enough to bring the tube vacuum down to a point that would give with the same construction a discharge free from ionization at high voltages.

Q. 388. Now, if you will please continue the answer which I interrupted.

A. I was about to refer to the curves that he gives on page 483 of the Royal Society paper, and to say that they show the sharp rise which is characteristic of gas conductivity in his devices. These curves were plotted on the logarithmic basis at the Interference record page 1320, and Dr. Langmuir discusses this whole situation, beginning on page 1308 of the Interference record. I put the reference here merely for convenience.

Now, I think you also asked me, Mr. Davis, to refer to Mr. Waterman's testimony on the Fleming valve in the suit brought by the Marconi Wireless Telegraph Company against the DeForest Radio Telephone & Telegraph Company under the Fleming patent, No. 803,684, which patent is our Exhibit No. 15. Do you want me to point out the parts of Mr. Waterman's testimony that I think have a bearing on this particular discussion?

Q. 389. Yes. Mr. Darby, I think, read some parts of it on the pages, which I indicated in my question, namely, pages 1486 to 1489, and I would like to have you say anything which you have to say which casts light on this deposition, and make any further quotation which you care to make from that deposition, but only from that deposition.

Mr. Darby: I have no objection to the witness making quotations from any part of the testimony, but I do not think the witness can explain this testimony.

Mr. Davis: If your Honor please, the only explanation which would be possible to have would be as to the use of terms at that time. The terms are used in the portion read by Mr. Darby and which to our ears in this trial have a certain standard of things and mean one thing, which may, and I believe did mean, an entirely different thing in that trial.

The Court: Can you control the testimony? Is it the intention to restrict the testimony to that?

Mr. Davis: Absolutely, your Honor.

Mr. Darby: There is no objection to that at all if the witness is cautioned that that is the purpose of it.

The Witness: On page 1088 of the printed transcript in the Marconi case, XQ. 218:

"What is the pressure in the bulbs used in the detector sets of the Marconi Company?"

Then follows for a page a discussion of detector sets, and so on, and the answer to the question comes in answer to XQ. 225, where the question is:

"I mean, give the actual pressures, what is it in millimeters of mercury, the ordinary way we use it in respect to lamps of this kind?

A. The pressure as I understand it is always less than one one-hundredth of a millimeter of mercury, usually as low as one one-thousandth and oftentimes so high that no test whatever will show the presence of any gas, no known test."

The two pressures correspond to ten and one microns respectively, as the pressures used in the device.

Q. 390. Let me see what year was that testimony given in, Mr. Hogan?

A. 1919, I think. I will have to check up.

Q. 391. 1916?

A. The record does not seem to print any dates. You are right, Mr. Davis, "Adjourned to March first, 1916," is at the bottom of page 996, just before the part I was quoting. At page 1102, the Court inquires to how good or how bad the vacuum could be, and Mr. Waterman's reply is:

> "I do not know. I do not pretend to be an ultimate authority and encyclopedia on this whole subject. I only know that in the course of the tests which we made, immediately for the purposes of this case, we made several hundred bulbs and we had air pressures all the way from atmospheric down to as nearly an absolute vacuum as we could get, and that they did not begin to act in a way which could have been even thought of at all for commercial use, until, well, I am a little hazy about that, but my recollection is that the presure was one-tenth of a millimeter; and they did not begin to be of any use until the pressure was a good deal lower than that. That established conclusively that what you want is a vacuum, a real vacuum, in incandescent lamp vacuum.
>
> XQ. 262. That is a real vacuum?
>
> A. It has always passed as such.
>
> XQ. 263. It does not need to be any lower pressure than that?
>
> A. Does not need to be any lower pressure, but it is very nice to have a lower pressure. You can get along with an incandescent lamp vacuum in very good shape indeed."

The pressure at which he began to get results, namely, one-tenth millimeter, corresponds to 100 microns.

Now, on page 1105:

> "XQ. 274. All right. Never mind answering if you do not want to, without taking up the time necessary to make all those distinctions, what is the pressure of an ordinary incandescent lamp?
>
> A. Mr. Pickard stated that it was from one one-hundredth to one one-thousandth of a millimeter, and that corresponds to my understanding. The present tungsten lamps are rather better than that, but that is a general definition."

The two pressures there, one one-hundredth to one one-thousandth of a millimeter again correspond from ten microns to one micron, which checks very well with our understanding here of the vacuum of an incandescent lamp.

The end of the answer to XQ. 279 on page 1107, is in connection with the general question as to X-ray tubes, and reads:

> "In the Coolidge tube, where you have the hot electrode and the absolute vacuum, there is no visible phenomena of any kind, that is, the X-ray tube which is revolutionizing things of the present day."

That is a statement of the "absolute vacuum" which has appeared in one or two other instances; in other words, the Coolidge tube vacuum, at which there is no visible evidence of ionization.

Page 1111, with respect to the White patent which is Exhibit 42 in this case, Waterman says:

> "In other words, it would appear that there is some special assistance there given by the trace of mercury vapor, but the vacuum is extremely high in these bulbs. It is an extremely high vacuum."

Then at the end of the page he says:

"Or, in other words,"—this is after quoting a portion of the White patent descriptive of the old audions—

> "Or, in other words, when in the so-called audion referred to here, the ionization becomes evident, then the bulb becomes useless, which is just what I said."

I think that gives us a better idea of what Waterman meant when he referred to a high vacuum and an absolute vacuum and an incandescent vacuum.

Mr. Darby: I would like to have the remainder of that answer read in. I think the remainder of it explains the passage that Mr. Waterman has just testified to.

By Mr. Davis:

Q. 392. Will you please read the rest of that answer on page 1111 and 1112?

A. Yes, certainly:

> "I have not for a moment denied that there were ions in there; nor have I denied that they are of a certain usefulness. On the contrary I have stated the theory. But just as soon as ionization becomes ionization which can be conducting; that is, as soon as ionization takes place in the path between the grid and the filament, then the valves go out of business, and I think very likely it might be very instructive to the Court to demonstrate that.
>
> "In these bulbs you will find as you urge the voltage up; that is, as you are working for the most sensitive point there will come a point where the signal disappears. In some bulbs this does not come suddenly, it comes gradually. In other bulbs, it comes all at once; the signal absolutely disappears. The better bulbs, the more satisfactory bulbs to handle are those in which the blue color comes gradually and not suddenly, and if you watch such a bulb critically you will find that as

you pass the point of good sensitiveness there is a little fringe of light begins to appear around the plate. It is between the grid and the plate along the edges of the plate. If you push it a little further you begin to see a blue which treads on the 'toes of the grid, so to speak, and then your signal quits. In other words, when the ionization action gets in between the grid and the filament, I mean the visible ionization action, I have never seen a bulb that would work; maybe there are some (I would not venture to make any positive assertion that a bulb could not be made to do anything), but I have never seen one. Just as soon as the ionization gets into the direct electron path, the effective electron path, the bulb stops."

Q. 393. Now, will you continue your answer?

A. I think the evidence of visible ionization there is——

MR. DARBY: I object to that. I do not think the witness——

MR. DAVIS: The witness has been asked to comment on a thing and say what the terms mean.

MR. DARBY: This witness was not asked as to any emphasis being there and I do not think the witness is qualified to state whether there is any emphasis.

THE COURT: The last statement is a volunteer statement and is stricken out. There is no question to the witness. If Mr. Davis wishes to ask a specific question, very well.

By MR. DAVIS:

Q. 394. I will ask you as a person skilled in the art and knowing the use of the terminology and the history of the art, what you say is signified by the terms highest vacuum and absolute vacuum in that deposition?

A. He defines that as a vacuum in the Coolidge tube. He says that is the closest approach to an absolute vacuum that he can get.

Q. 395. And when he speaks of conduction by ionization in the portion which you last read, what does that signify to you as one skilled in the art?

A. He defines that by saying that he means visible ionization, that is to say, ionization accompanied by blue glow. That is in his own words.

Q. 396. Now, will you continue with a discussion of the references?

A. Exhibit 17 is the Soddy Patent 859,021. I have discussed this patent with relation to the last three patents beginning at page 1577 of the record. This is the magnesium or calcium pump and I think Mr. Darby said it was not cited against the first patent but I also believe that Dr. Chaffee included it in his classifications of baking the walls, heating the electrodes and bombardment.

When it is used on a lamp—when the pump is used on a lamp Soddy proposes heating the filament, but of course there is no anode. When it is used on an X-ray tube there is heating to the extent of operating the tube. In the old X-ray tube, one of course must not have gas free electrodes or the tube would be more critical than ever. If we recognize that the pumping efficiency goes down, decreases, as the pressure goes down in a pump of this type, it is perfectly clear that it is simply another type of pump, this time a chemical one, which will attain a lamp or X-ray pressure of a few microns.

Exhibit 18 is the Soddy article in *Nature*, November 21, 1907, which I discussed in connection with the last three patents at page 1579 of the record here.

Here we have a description of an experiment in which there was no heating of the bulb, and no freeing of all the electrodes from gas, although running the filament and running the anode with an ionization glow present might have conceivably done the anode some good, and certainly would have helped the filament to some extent. Whatever vacuum Soddy got did not stay, for he says at the bottom of page 53, after a little while a very feeble glow started. That is, after the current had stopped. And he says that this was probably due to a further slow evolution of gas from the still heated surfaces. That appears at the top of page 54. Then he refers to more gas that was then generated within the apparatus by heating the third electrode. That is the first part of the first complete paragraph at the top of page 54.

Whatever vacuum Soddy got at the instant of the current stopping even, he did not investigate it, he did not use it, and he did not find out what the current was, or what the law of current was in it; and the cessation may well have been due to wall charges on the tube rather than anything else, but of course we do not know positively. All we know is that whatever was had was purely temporary. Dr. Langmuir discussed that publication at page 1510 of the Interference record.

Exhibit 19 is the Lilienfeld reply to Soddy in the *Physikalische Zeitschrift*, and I will take that up later in connection with the other Lilienfeld publications including Exhibit 31.

Exhibit 20 is the article by Hogg in the proceedings of the American Academy of Arts and Sciences for August, 1909. This describes work in which Hogg was working with a tube having no electrodes and a tube that was not removed from the pump. It was for the purpose of observing pressures and the mechanical effects of gases rather than their electrical effects.

Dr. Chaffee quoted from page 9, where the pressures were indicated as less than one one-thousandth micron, but on reading the paper as a whole I find that Hogg seems to have a good deal of doubt about the accuracy of such measurements even with the special McLeod gauge that he had; and of course that is reasonable because it is very, very difficult to read differential levels of mercury when those differential levels come down to less than half a millimeter. In any event, there is no suggestion that whatever vacuum was obtained, whether it was as low as this or not, could be obtained in a tube having electrodes, and there is no suggestion that if it were obtained it would have any utility nor that it could be maintained in a tube that had sealed off, this one having remained on the pump.

Exhibit 21 is the *Annalen der Physik* 1910 article by Hupka, which I discussed at the record, page 1584. This is illustrated by Dr. Chaffee only under the vaporizable reagents and alkali earth metals classification and is the paper in which Hupka said that he had tried the Soddy process, but that it was not adequate for his purpose. He indicated that he could get a hard X-ray vacuum at the moment of vaporization but nothing more. I have already commented on the process of Hupka with regard to present-day devices and I think that beyond noting that, although he used charcoal and liquid air, the device was a photoelectric tube which of course had extremely small currents, and probably it is not necessary to go into this further.

Page 185 refers to two cemented joints in the tube and page 184 refers to the fact that aluminum was chosen for the diaphragm because it gives off the least gas in a vacuum. There is a quartz window on the tube, white cement was used and he observed fluorescence in his experiment, fluorescence of the glass walls of the tube.

I think all of that goes to show that low pressure was not attained and it is clear that he did not suggest any utility for it in any such arrangements as are used today and have been used since Langmuir's application.

Exhibit 22 is an article by Von Baeyer, appearing in the *Physikalische Zeitschrift* for 1909, page 168. Dr. Chaffee said that this shows an electron-emitting cathode and that the ions present were measured by the third-electrode test. He also referred to the securing of a vacuum in the device by the use of charcoal and liquid air. He did not include the publication in any of his classifications as to baking the tube and so on. I think he said there were no data to compute the currents used.

At page 170, referring to elimination of mercury vapor Von Baeyer says: "I did not succeed, however, by the condensation of mercury vapor which was attained by the cooling . . . . in appreciably reducing ionization."

This is a condensation trap, with the use of liquid air, but that particular use is not in connection with absorption by charcoal. On page 171 he points out that there was ionization above 10.4 volts and very little below that voltage, and consequently he worked below ten volts. He thought that might be due to mercury vapor but found that the ionization was not reduced when it was cooled with liquid air. When he used charcoal and liquid air together he increased the vacuum, and the ionization could not be measured (as he says) with not too high velocity or at velocities not too high; that is to say, at accelerating voltages that were not too high.

There was some reference to his having had no measurable ionization at forty volts on one of the electrodes and to the effect that those forty volts were above the ionization voltage, but page 174 shows that this was a negative voltage applied to the counting electrode and it had no reference to the positive voltage that would produce the ions.

In other words, having already shown that he got all the ions to the counting electrode at twenty volts the increase to forty volts is not significant. At page 171 is the place he said that the ion currents did not increase with increased negative potentials on the negative electrodes.

As to the currents used, the table at page 170 shows a maximum deflection of 20,000 and refers to footnote 9, where he points out that these large deflections are not directly observed, but calculated from the deflections with properly chosen shunt resistance. Knowing the sensitiveness of the galvanometer as five times ten to the minus tenth amperes per division, we may find these currents from the deflections that he has given. That 20,000 deflections means ten-millionths of an ampere, ten microamperes. There are a few higher readings on the same page and that would correspond to approximately fifty microamperes, all extremely small currents.

This publication is discussed by Dr. Langmuir in the Interference record at page 1458.

Exhibit 23 is Thatcher U. S. Patent 1,028,636. This patent Dr. Chaffee referred to as showing the so-called filament clean-up to get high vacua as he said without vaporizable reagent in the tube. Thatcher brings his filament intensity up to a point that produces a glow in the tube, so that of course it could not be used with low voltage filaments as used in tubes. I think that was pointed out in connection with the Whitney paper which gave a limiting voltage of fifty or something of the kind.

We all recognize that the blue glow in an unbaked tube or without well-treated electrodes may give off as much or more gas as it tends to clean up while the filament vaporization is going on. Thatcher points out that instead of pumping to two millimeters, that is to say, two thousand microns, as is done by the Malignani process, and then depending on a chemical clean-up, Thatcher will pump down to two-tenths of a millimeter (which is 200 microns) on a mechanical pump and complete the exhaust by the intensive incandescence of his filament. That reference is at page 1, lines 88 to 98. On page 3, lines 29 to 35, he recognizes a rather limited range of clean-up that is possible by this vaporization process without too much disintegration of the filament.

On page 4, lines 3 to 5, he says that the disappearance of the blue haze may be relied upon to indicate attainment of the requisite high vacuum. That of course defines his vacuum as a lamp pressure of the order of microns.

I might point out in this connection that in a lamp bulb gas comes out of the filament very quickly and heating the wall, if that is done, will give off a great deal of water vapor and some carbon dioxide and some nitrogen, probably less of nitrogen than of the others. However, the action of the filament on nitrogen is not very rapid at normal temperature, the temperature of the filament has to be pushed up to a point where it would have a very short life in order to clean up nitrogen in the tube.

Exhibit 24 is the Friederich Patent 1,083,677, which is an X-ray tube patent, and which was quoted by Dr. Chaffee in connection with ridding the electrodes of all the gas contained in the metal.

This tube is of the old-fashioned X-ray type and the idea that Freiderich discloses is for a better regulation of the amount of gas in the tube.

On page 1, line 50, immediately after the portion that was quoted he states:

> "The regulating device should not be on the outside of the tube but should be located within same near the center so that the gases absorbed

by the regulator may be easily liberated for the purpose of forming a passage for the current."

So I think we need go no further on that patent in connection with the patents here in suit. He certainly had a very different idea as to what "all the gas" in an electrode was, from the idea that Langmuir has stated.

Exhibit 25 is the Lilienfeld paper in the *Annalen der Physik* of 1910 and the *Berichte* of 1911 and I will take that up later.

Exhibit 26, is an article by Dember, July, 1911. He uses a photo-electric cathode and he kept his device on the pump all the time. His structure is shown at page 602 of the original and has two ground joints, seals of the laboratory type, and a window sealed to the tube, and he speaks of the use of a wire gauze D (at page 604 of the original paper) for the purpose of preventing positive ions formed by collision ionization of the residual gas from entering the adjoining tube.

Your Honor will see the screen D here and that was to keep positive ions formed by collision ionization from entering this tube. That sort of performance is to be expected in spite of a gauge reading of one-twentieth of a micron to which Dr. Chaffee referred, if that is in an apparatus with untreated apparatus and wax joints. I think the last sentence of the paper refers to gas occluded in the metals.

The paper is discussed by Dr. Langmuir in the Interference record, page 1474.

Exhibit 27 is the Gehrts publication, an extract from his preliminary dissertation, but this copy does not carry the date.

Here again we have a photo-electric experiment in which the tube has two ground joints or sealed joints from which vapors may well escape, and while he may have had a low pressure or a fairly low pressure while the pump was in operation, the device was not taken off the pump and certainly could not have held that pressure if it had been.

It contains a good deal of untreated metal and even with the small photo-electric currents that he used, there was doubtless a good deal of ionization. A statement on page 13 of the translation speaks of the production of carriers, which is the production of ions, and gives data for ionization measurements, together with the statement:

> "Up to highest velocities used, there was no trace of ionization."

That sentence, I think, was quoted by Dr. Chaffee, but immediately afterward the article points out that it was conceivable that ionization, which would be noticeable at full photo-electric intensities, escaped observation in these particular measurements, because he had cut down the intensity of light on the screen when he made those observations.

When he was operating at normal light incidence, he apparently got ionization which he referred to at page 14 of the translation:

> "Thus the error caused by impact ionization is surely less than one per cent. and may be disregarded in the above measurements."

That would seem to indicate that he considered one per cent. of the space current carried by ionization, as having no effect on his particular measurements, and he may have been right on that; but one per cent. of the total current carried by ionization in a thermionic tube, would mean destruction of the space charge, and would be a tremendously high gas reading, so-called. If he got any such ionization as that at these small currents that he is using, it certainly is indication of extreme ionization occuring at large thermionic currents.

Q. 395-98. On that point, Mr. Hogan, you are referring to the action of the ion in neutralizing more than one electron; is that correct?

A. Yes.

Q. 399. Will you proceed?

A. Dr. Langmuir discussed this paper at Interference record, page 1463, and Dr. Millikan also discussed it at the end of Q. 8 in the Interference, where he said that Gehrts had a negligible ionization in the sense that the ionization of the current was less than one per cent. of the electron current.

The next exhibit is No. 28,—U. S. patent No. 1,205,022, issued to Marshall in 1916. I discussed that at page 1586 in connection with the last three patents in suit, and it is merely a way of attaining a pressure of a few microns in a lamp, following the Malignani chemical exhaust idea.

Exhibit No. 29 is the Child paper in the *Physical Review* for 1911. He is here investigating what causes the increased current in a vacuum tube when the luminous discharge begins, and he gives both a theoretical analysis of that and some practical experiments, from which he reaches his conclusion. He attacks the problem from a point of view that the large current observed in the luminous discharge of these tubes could not be carried by positive ions, only because they would, so to speak, get in each other's way and prevent the flow of a large current carried by particles or carriers of one sign——

THE COURT: Of what?

A. One polarity. He worked out for these positive charges the mathematical relation, (which he states on page 500 gives):

> "the largest current which it is possible to have carried by positive ions,"

for a given distance, and a given electromotive force; and we recognize now that the mathematical form of that equation is unchanged, if, instead of the positive ionization that Child was investigating, we use our more recently acquired knowledge, and apply it to negative electrons only. In that case, of course, it has no relation to the luminous discharge which Child was attempting to explain or investigate.

After he reaches this relation, he points out that the greatest amount of current that additional positives could carry, after a certain current had been assumed as necessary to neutralize the current carried by electrons, would not be enough to account for the greatly increased current as the luminous discharge begins, and so then, in a section, beginning at page 501, headed:

> "Increase in Current not due to Change in Field."

He takes up the possible effect of the negative charges and the positive charges to each other. He says:

> "it is conceivable that it (the increase) is due to a change in field produced by them"—(the positive ions) and that "When there is no ionization of the gas, the electrons coming from the cathode may be so numerous as to reverse the direction of the field in part of the space."

And he thinks that that could actually occur in practice. He goes on to show from the data taken with an exploring electrode, the results of changing from a calcium oxide cathode to a clean platinum cathode, and then on page 505, he gives what he calls the correct explanation. And on page 510, what he calls the summary, he says, at the bottom of page 510:

> "The phenomena may be explained by assuming that ionization is produced at the cathode by the bombardment of its surface by positive ions

and that such ionization occurs very much more easily with a very hot cathode than with one which is cold."

That is his explanation of the large increase of current when the blue discharge in the tube begins, namely, the more complete or easier ionization emission, the emission of ions by the hot cathode under these conditions.

In the paper there is no work at low pressures, no experimental work at low pressures. I think the lowest pressure recorded is fourteen microns.

That is natural since he was investigating the glow discharge, and the whole question of positive ionization.

Theoretically, that is as to the theoretical part of the paper, there is no suggestion that his mathematics could be applied to the electron current so far as I can find. That is a thing which we learned later. There is no suggestion that the increased current in the tube is really due to neutralization of an electron field by positives. Practically, his work was with high pressures, with discharges, which even when they were non-luminous, nevertheless, were strongly ionized (because we recognize that the disappearance of the luminous discharge does not mean the disappearance of ionization), and all his work, both theoretical and practical, resulted in his acceptance, of the conclusion that I have read from the next to the last page of his paper.

Now, Dr. Langmuir discusses this paper at page 1013 in the Interference record.

The next exhibit is No. 30, which is a paper by Majorana, published in 1912. Majorana, according to the paper, built a duplicate audion and exhausted it and took some characteristic curves. Those curves are plotted on a very small scale at page 238 of the original article. He took the curves under three conditions

—first with grid to positive filament (that is what he calls on the curve "grid neutral"), and he gives the filament voltage as 3.8; therefore, this "grid neutral" curve is taken with the grid actually at the positive potential of 3.8, and consequently causes current to flow in the grid circuit through the tube. The second curve going from the top down is marked "grid negative," and in that case he put ten volts negative potential on the grid; but he did this from the positive terminal of the filament, so that there was a net potential of ten minus 3.8, or minus 6.2 volts on the grid. The third curve is marked "grid positive" and that is taken with a voltage of ten positive on the grid; so that the actual grid voltage with respect to the negative end of the filament is 13.8, that is the sum of the grid battery and the filament voltage drop.

He concludes from the three curves (which show lower currents for the same plate voltage, whether the grid is charged negative or whether it is charged positive). He concludes that charges, either negative or positive, applied to the grid will cause a decrease in the plate circuit current; and curiously enough, for the same reason that misled DeForest in his 1913 paper. That is to say, by the application of too high a positive potential to the grid, and the failure to measure the electron current which that drew to the grid, Majorana has made the same mistake as to the theory of the audion as did DeForest. He shows and states a reduction of plate current for either positive or negative charge applied to the grid, and that, of course, is not the way an audion works, and if it did work that way, it could not be used for amplification, or any of the work that flows out of amplification.

I mention this because the only curve here upon which one is entitled to draw any conclusions, is the one marked "grid negative," that being the only curve for which no current flowed to the grid. When the grid is at the negative end of the filament, there is no tendency of course for the grid to get current except by ionization.

The other two curves can not be used to give a basis for an understanding of the tube, certainly by the application of the 3/2 power law, or any of the other tests, because we have no data as to the amount of current which was diverted from the plate and caused to flow through the grid circuit by means of the grid potentials.

Now, Dr. Chaffee said that these curves did not indicate any ionization up to 50 volts, but I think he must have overlooked the situation with respect to the positive connection to the filament of the grid, because if one plots the data from Majorana's "grid negative" curve, as well as it can be taken from the small sketch, there is a characteristic rise of slope in the neighborhood of 15 volts, which makes it quite clear that ionization came in to the Majorana tube and that he really succeeded in duplicating the DeForest tube, not only as to dimensions, but also as to the amount of gas present.

The next exhibit of the defendant is the Lilienfeld-Rosenthal article of 1912, published——

By Mr. Davis:

Q. 400. I just want to suggest that might be a long part of the answer, if your Honor wants to take a short recess?

The Court: Very well; we will take a short recess now.

(After a short recess.)

A. This Lilienfeld-Rosenthal paper, Exhibit No. 31, has to do with the so-called first Lilienfeld X-ray tube which your Honor may recall, as shown at page 257 of the article in German. I agree with Dr. Chaffee as to that tube, that there must be sufficient positive ions present to maintain the main or X-ray producing discharge, that is to say, the high voltage discharge. Now, as to the auxiliary discharge so-called, that is the discharge between the hot electrode, the hot cathode, and the cylinder anode in the tube, not the X-ray anode, I think it is perfectly clear that currents as large as 180 milliamperes, which is the sort of current that Lilienfeld got in that discharge path could not flow if there were space charge limitations there, nor if the discharge tube were sufficiently free from gas so that the negative grid action, or current—stopping action, of the 30,000-volt main cathode could act upon the auxiliary discharge. Dr. Langmuir explained both of those points in detail, at page 1276 of the record here, and I do not see any need of repeating them now.

This first Lilienfeld X-ray tube is illustrated, in fact I think the cut is the same, at page 212 of the *Hand Book of Radiology*, by Marx, dated 1915, and that hand book with respect to Figure 69, which shows the first form of Lilienfeld X-ray tube, states as follows:

> "The arrangement has, however, two disadvantageous features. Firstly, the current strengths in the primary discharge exceed by far the current strengths in the secondary discharge. Secondly, moreover, the high voltage secondary discharge influences the primary discharge which operates with relatively lower voltage drop in such a manner that surges occur, especially if it is desired to obtain very hard rays. The high voltage occasionally quenches the primary discharge, and it is not very easy to avoid these disturbances by inserting high voltage resistances and similar devices."

That is a practical demonstration of this current stopping effect of the high voltage cathode to which Dr. Langmuir referred, and it is described in this publication as occurring in the attempt to get very hard rays, which of course is the higher voltage operation, because the penetration goes up as the voltage is increased.

Later on the next page, page 213 and page 214, with reference to Figures 71 and 72, which show later forms of Lilienfeld X-ray tubes, the author says:

> "Finally, the fluorescence of the front half of the sphere which otherwise exists in tubes does not occur."

That is in these tubes of Figures 71 and 72, and,

> "This shows that no reflected or secondary cathode radiation reaches from the focal spot to the glass sphere."

The absence of glass fluorescence in the second and third forms of the Lilienfeld tube, therefore, is worthy of comment in relation to the operation of the first tube; and I think that it has been stated in this record, but for fear that it has not I had better say so, that if a discharge is practically free from ionization and occurs at high voltages, high speed electrons will hit the glass under conditions where they can reach the glass, and will start to make the glass fluoresce. However, they will charge the glass negative on their arrival and consequently no more electrons will arrive at high speed and consequently the glass will not fluoresce when the negative charge remains on the wall of the tube.

On the other hand, if there is substantial ionization such as would destroy the space charge, then the wall charge may also be destroyed, that is to say, the accumulation of negative charges on the wall may be destroyed by the positive ions (or it may even become positive) and in that case the fast-moving electrons will hit the wall and cause ionization. That is the way in which fluorescence may be a sort of test for the presence or absence of ionization.

There is another publication with reference to this Lilienfeld tube and that is an article by Lilienfeld himself in the *Berichte* of the Academy of Sciences of Saxony, 1914, pages 76 to 79.

This shows a photograph of the second type of Lilienfeld X-ray tube at page 77 and in connection with the production of that type of tube points out that in order to do away with starting potentials, so to speak, one has to get electrons from the cathode without relying upon the main field to do so. It is a sort of an introductory statement to his general discussion of producing of electrons.

He says: "One must use a glowing electrode to get such a discharge condition." And when I will quote from the translation: "It remains now only to consider how we can prevent the electro-static field around the cathode from unfavorably influencing the discharge coming from the incandescent electrode and necessarily passing by the cathode. Such an unfavorable mutual influence of two gaseous discharges always occurs if the carriers of electricity which provides the current conduction get into a field which crowds the carriers of electricity from their path. Consequently we have the simple principle that if two gaseous discharges are to occur simultaneously, their electrostatic field must show the same direction and the same sense. From this knowledge follows the construction of the tube." And he refers to the new tube in which your Honor will see that the filament, cathode and anti-cathode are in line, so that this "reaching in" effect or grid effect of the high voltage negative no longer occurs in this tube.

These two references have to do with the change from the first form of Lilienfeld tube to the second and third forms and both refer to the effects of instability that Dr. Langmuir described in connection with the grid action of the third electrode.

There was some attempt to prevent the stopping of the auxiliary discharge, that is to say, the filament discharge, by increasing the voltage applied to the anode of that filament discharge to about 500 volts and I thought that was referred to in the Lilienfeld-Rosenthal paper, but I am not able to find it at the moment.

The situation is then that even in the auxiliary discharge of 'the Lilienfeld first type of X-ray tube, there must have been ionization rather than control of the amount of current by space charge. The situation then with respect to the tube becomes that he approaches, as he said, an X-ray tube which would operate at pressures somewhat below those pressures at which an ordinary X-ray tube would stop operating but clearly not at such pressures as would stop the auxiliary discharge, because when that would tend to stop by further clean-up, the whole tube went out of operation and the unstable effects occurred.

Mr. Davis: With your Honor's permission, I will now interrupt the examination for the sake of asking Dr. Arnold some questions. Dr. Arnold, will you take the stand?

John V. L. Hogan, resumes the stand:

Direct Examination (Continued).

By Mr. Davis:

Q. 401. I think you have dealt with the Lilienfeld-Rosenthal article.

A. That is correct. That first X-ray tube was, I believe, the first practical device that Dr. Lilienfeld suggested. The 1910-1911 papers in the *Annalen der Physik* and the *Berichte* refer to the experiments on the rather complicated form of tube with exploring electrodes. Your Honor may recall Figure 6 on page 685.

By The Court:

Q. 402. Those sounding electrodes?

A. Yes, your Honor. That tube, of course, was not a tube made to do work. It was for a scientific experiment and it was never sealed off of the pump so far as I can find. There is some reference in the *Berichte* paper to the use of a glass valve which cut down the rate of diffusion of gases between the pump and the tube and that is shown, I think, at page 435 of the *Berichte* paper, but, of course, that is a very different proposition from a sealing off and maintenance of pressure under operating conditions in a sealed-off tube.

Lilienfeld in the text says that he had plenty of positives present, to put it colloquially, that is, he made the explanation that there were as many positive charges present as there were negative charges and of course he insisted that because of the care he took in evacuating his tube that his positive charges could ~~not~~ have been due to gas ionization.

He advanced the theory and seemed satisfied with it that the empty space within the tube dissociated into positive and negative charges; and that is a theory which nobody from his time to now has been able to bring himself to accept, if only because they asked themselves the question, after space is dissociated into positive and negative charges, what is left? It just does not mean anything to any of us nowadays.

A much more plausible explanation of the presence of the positives is that there actually was either vapor from the hot glass walls of his constricted tube or that there was some gas present that would have been ionized at the very high voltages he used, in spite of his efforts to get extreme vacuum.

He does not give us any measurements of the over-all voltage on the tube, but his earlier papers refer—and I think this 1910 paper also refers to the high voltage machines from which he derived his potential.

Across the short distance of the sounding electrodes he measured drops up to about 400 volts and I think all the evidence together with the fact that he referred to using series resistances of values varying from something like 11,000,000 ohms to something like a thousand million ohms, if my recollection on that point is correct as to the figures, I think all of those things go to show a high voltage applied to the tube of the order of thousands of volts certainly, and tens of thousands of volts probably.

Under such potentials and even with vacua that were high compared to those used in X-ray tubes or any of the common experimental tubes of Lilienfeld's time of 1910, I think that gas would be the most natural way to account for the positives that he said were present.

There has been evidence argued in discussion of these Lilienfeld papers of 1910 and 1911, to show that he had no gas, but I think that all of that is argumentative and indirect. One point that has been made is that there was no difference stated as to the current voltage relation of the discharge as the pressure was reduced. In other words, if one takes one relation between voltage and current (as determined by Lilienfeld), and another one as determined by him when he had changed the pressure in his tube, for instance, by applying liquid air or something of that sort, one finds that those current voltage relations are unchanged.

That was said to be analogous to or the same thing as the criterion which has been described in connection with the Langmuir tube, namely, that you knew you had a good ionization free discharge when you found that reducing the pressure in the tube did not affect that discharge, or rather, its law of voltage with respect to current, to a material extent.

In the Lilienfeld case the discharge which was not affected (or the law of which was not affected) as the pressure was changed, was not the main discharge and that point I hope to make very clear.

In the Langmuir case we are talking about the voltage current relations overall, that is the real useful discharge of the tube. In the Lilienfeld case he was talking about the current voltage relation between these sounding electrodes, and it was not even the current that flowed into the sounding electrode circuit but the current that flowed past the sounding electrode circuit.

Your Honor may recall that the electrodes were connected to an electrometer so that no current flowed in their circuits. Therefore, although as a matter of words those things sound alike until one analyzes them, as soon as we get into the facts we find they are quite different.

If Lilienfeld had given us the changes in voltage over the tube and the currents through the tube and had had as a result of that data a law that indicated that there was no change in the current-voltage function as the pressure was reduced, it might have been in the absence of other factors a fair assumption that he had an ionization-free discharge or a substantially ionization-free discharge.

On the facts here, however, since those measurements are subject to all the errors that probe measurements can be, I think the criterion is a false one as to this case.

There was a second criterion, a second piece of indirect evidence which has been argued to show that the Lilienfeld experimental tube of 1910 was operated in the absence of gas ionization and this, your Honor, in spite of the statement by Lilienfeld that electrons did not predominate, that he had equal numbers of positive charges. The second point is that with the device there was attained a constancy of current as the filament temperature was increased.

Lilienfeld said if his filament were hot enough it did not have to be hotter, or that it made no difference in the discharge if he once got it hot enough whether or not he increased the temperature. That has been called the flat top temperature curve, which is a demonstration (in the case of a measurement of the overall discharge) of the ionization-free condition, because with a properly observed and stated flat-top temperature curve, we know that the saturation portion has been left and that something other than saturation is controlling the amount of current passing through the tube. That other thing is in general space charge and that is the controlling agency, the current limiting agency in the practical tubes of the Langmuir patent.

An effect which is a little bit similar in its superficial aspects to the flat-top temperature curve may be had from an altogether different cause if one has in series with the devices being measured, a high external resistance, because the change in the tube current with the filament temperature does not go up indefinitely when a voltage drop commences to develop across that resistance by reason of the current passing through it multiplied by the resistance itself, and commences to be subtracted from the voltage supplied to the tube.

One may offset the other so that an apparent flat-top relation is had. I think in so far as we can tell from the data given us by Lilienfeld that this statement of his may be fully accounted for by the high series resistance, and the measurements that he took between his exploring electrodes instead of on the main discharge.

A third point that has been argued to show that Lilienfeld had no gas in his tube was a statement that his current was limited by space charge. Lilienfeld himself in the *Berichte* article emphasized his conclusion that there was no space charge in his tubes and I cannot see that measurements taken by exploring electrodes in the narrow tube where wall charge, that is to say charges on the constricted walls of the tube, may have a prominent effect, I cannot see where measurements taken at such a place in the absence of similar measurements taken for the entire tube as bearing on its full discharge, can be used as an indication that there was space charge limitation.

Lilienfeld did not seem to think so and I do not think it is properly arguable now.

The fourth point that has been made was that the Lilienfeld discharge at some part of the range from lowest currents and voltages to highest currents and voltages followed the 3/2 power law that was propounded by Dr. Langmuir and which is used often as a test of a working tube.

In the first place, there has been no agreement between the witnesses in the Interference and those here as to where on the Lilienfeld curves that 3/2 power law applies. Dr. Chaffee here said that the point at which the 3/2 power law is to be taken is down at the bottom of the curve, in the initial sloping portion of the curve where curvature is changing, and that he tied up with Lilienfeld's statement that the variation of current as the 2/3 power of the voltage, Lilienfeld, of course, deriving that relation by the insertion of a constant and various changes in the curves.

Richardson in the Interference replotted some of Lilienfeld's data and found an agreement with the 3/2 power law over a high voltage range over in the portion of the curve that Lilienfeld said followed the square law.

I do not think it matters where if at all the discharge in Lilienfeld's tube shows indications of agreement with a 3/2 power law over a limited range when we remember that what we are talking about is the main current through the tube, and not that passing by a pair of probe electrodes as related to the voltage measured between those probe electrodes.

In other words, no matter what part of these characteristics taken by Lilienfeld we may use, we are in no event taking the current voltage relation of the main discharge. That is the important thing in the Lilienfeld tube, the tube of the Lilienfeld article, and by that I mean the main discharge and its voltage current relations. And I think it is technically unsound, and that is putting it rather gently, to use probe measurements (of probe voltages where no current flows) against main current flowing past the probes, to derive any current relation applicable to a main discharge.

If one replots the Lilienfeld data and takes out the "correction" that looks like eleven volts but is really something very much higher, he finds that even between the probes the voltage current relation starts off, instead of agreeing with the 3/2 power, it starts off something like the 20th power and then slows down, that is, the power slope of the curve becomes lower.

Of course, any curve passing from a high power to a low power is going to come for a part of its range through any exponent you may choose that lies between the extremes, and I see no significance beyond that, of the characteristic curve relation—even if we should assume for the purpose of the argument that measurements taken between the probes and not across the entire tube were of any real significance.

Considering the tube itself, there was an experimental apparatus that was used on the pump or while cooled by liquified gases and in that tube Lilienfeld probably got an unusually high vacuum, a vacuum higher than that common in the tubes of the day.

He did not use it or suggest its use for a pure electron discharge so far as we can tell from the publication. He gives no data on his main discharge current relations and he did not take his apparatus away from his vacuum producing means.

He got no current through his tube at all until the overall potential reached a value of something like 105 volts measured between the probes. What that meant in the outside potential we cannot tell but it must have been exceedingly high. That is totally unlike any tubes of the Langmuir patent that I have ever seen.

Further, he had a starting electrode shown at Z in this Figure 6 at page 1685, the use of which is not explained by him but which from its name and position is probably analogous to the starting electrode that was common in the mercury arc ionization devices and which was used in the Arnold tube as described in one of his patents that has been put in.

I cannot see that Lilienfeld added anything to the practical art in the way of accomplishment or suggestion. What one can find in his paper by looking back at it now is rather slight, and even its effect was undoubtedly discounted by the muddy statements—the lack of clear-cut statements and by the false theories, or at least the theories which we have not yet been able to accept, that accompanied it.

> Mr. Haight: I do not know what the line of objection has been or the line of ruling, but it seems to me that that part of Mr. Hogan's answer that begins with "I cannot see that Lilienfeld added anything" to either the practical art, and from then on is objectionable and should be stricken out.
>
> The Court: Motion granted.

A. (Continued.) Turning to Exhibit 19, which is Lilienfeld's short note in the *Physikalische Zeitschrift* 1908, page 193, we find that this is a suggestion that is directed to the Soddy experiment of Exhibit 18 where the current suddenly stopped and then started again, where he vaporized his magnesium or calcium anode, and we find Lilienfeld's suggestion that space charge was what limited the current in Soddy's work, this particular bit of Soddy's work.

We know now that if there had been any such space charge limitation in the Soddy tube it was probably due to charges on the wall of the tube rather than to a space condition.

Dr. Langmuir has discussed all three I think of these Lilienfeld publications and certainly the 1910 and 1911 publications in the Interference transcript beginning at page 1364.

Defendant's Exhibit 32 is an article by Kunz and Kemp in the *Physikalische Zeitschrift* for July 1, 1912, beginning at page 593. I covered this in connection with the last three patents at page 1587 of the record.

Dr. Chaffee includes the publication only in his list having to do with vaporizable reagents and I think it is perfectly clear from the publication itself that the highest vacuum attained was that corresponding to an X-ray pressure of a few microns. The authors speak of blue glow, violet layers, and the yellow sodium light observed within the tube on their spectroscopic analysis.

Exhibit 33 of the defendant is the Whitney article of 1912 in the A. I. E. transactions. I covered this at page 1588 with respect to the last three patents in suit and I see no bearing on the first patent because it has to do with lamp practice only.

Perhaps I should point out that even though a lamp in running its life does clean up beyond the exhaust value, that is, the value at which it left the pumping systems, to a relatively small fraction of a micron, no such effect would be available in a vacuum tube which must work from the moment it leaves the factory.

You cannot rely on a long time clean-up of that sort. If a vacuum tube had untreated anodes they would give off so much gas as to make the filament clean-up unrecognizable. One thing would more than offset the other.

Exhibit 34 is the Clark Patent 1,121,802, and that is the Mirror patent that I referred to at page 2634 and I do not think it would be worth while to discuss it further.

Exhibit 35 is an article by Angerer in the *Annalen der Physik* 1913, pages 1 to 26. It has a late date, 1913, with relation to Langmuir's work and the vacuum measurements in it are very doubtful, although measurements of what are apparently very low pressures are included in the text.

The author made two forms of tubes both of which are rather complicated and contain a great deal of untreated metal and also a number of parts covered with rust which is rather difficult to imagine in the interior of successful tubes today. Throughout the apparatus sealing wax was used, one of the tubes contained water glass, and the article has many comments about rays emitted in diverging streams and about positive ions and gas molecules in the tube, so that I think that in spite of the notations as to vacuum the author's own statements that he had to extrapolate beyond the point which his vacuum gauge would read in order to get these lower figures, I think that taken with the references to ionization make it unnecessary to consider the article further.

Exhibits 36 and 37 are the Clough and MacKay patents which were both filed October 30, 1915, and which are both late with respect to the first patent in suit and also have nothing to do with ionization-free operation since they are on high pressure devices.

In general, a great many of these publications are simply plans for pumping, such as charcoal and liquid air in a side tube or attached to the main tube, and I would like to say that pumping itself is not a serious problem in the preparation of tubes that behave according to the Langmuir first patent, that is to say, the Langmuir tubes. A good laboratory pump, a Sprengel pump with a liquid air trap or with carbon dioxide—I think I spoke to Mr. Darby on cross-examination on this—a reasonably good pump would be enough to give a good tube provided the treatment of the anodes, and the glass and the filament, has been carried to the extent that is necessary to make it possible to pump the tube out.

It is not a case of pumpability or pump capacity but what the tube itself will give off in the preparation. An improperly prepared tube, one that has not been degased thoroughly, cannot be pumped out and be made to stay pumped out even on the best and fastest pumps that we can get today. I think that covers the question, Mr. Davis.

Mr. Davis: If your Honor please, there are certain citations—I prefer to call them that rather than references—which have not yet been put in evidence by the defendants, and I assume that if they ever are we may discuss them when they are put in.

The Court: You may have a chance to reply when they are put in by the defendants on sur-rebuttal.

Mr. Davis: It is hardly that. Mr. Darby stated he did not have copies of certain references.

By Mr. Davis:

Q. 403. Mr. Hogan, you may assume that there is testimony in this record that Dr. Arnold on or about

November 1st had a certain discussion with Mr. Colpitts and I think Dr. Jewett and that there were two phenomena among others which he discussed and one was the phenomena that when the B-battery voltage was too high the tube broke into a blue glow and under those circumstances it would not repeat at all or repeat very badly. The other phenomenon was that when the B-battery voltage was lower than that so that the tube did not break into blue glow, it was possible to converse and get amplification provided the voices were not raised above a certain loudness, however that may be, whereas, if it were louder then there also was an effect which was noisy and prevented the amplification from being carried on. Mr. Arnold spoke of this as a quite separate phenomenon which should be kept distinct.

Will you please state the technical facts underlying those two phenomena and the difference between the two phenomena? And I may add for completeness that there seems to have been referred to by some of the witnesses an intermediate condition between those two in which the tube broke into blue glow when it was talked into and not when it was not talked into.

A. Let us first think about overload, that is I think the condition that you mentioned second, as a matter of fact, but by overloading I mean the inability of a tube to continue satisfactorily to amplify as the applied intensity increased.

Q. 404. That is, as a person talked louder?

A. Yes. Suppose one talked at a certain intensity and that resulted in a certain alternating voltage applied to the tube and we got as a result of that a certain larger response in the plate circuit. That would be a normal operation of the tube, the increase in response in the plate circuit being the normal amplifying function of the tube. Now then, suppose he talked louder, and that caused larger vibrations in the input voltage, so that the output current was called upon to pass through a larger swing or cycle than it was capable of doing, then the tube would be very severely overloaded, and would fail to amplify properly.

An extreme case of that would be where the plate current was of a definite value, say a certain number of microamperes and the current swing necessary to respond to the input energy properly employed would involve a change of more than that number of microamperes. It is perfectly clear that the current is not available in the plate circuit to cause a reduction down beyond the limiting point, the zero point, and the current can not reverse, of course; as I say, that would be an extreme case of overloading, that conceivably might have been experienced with tubes having a low plate circuit power limit.

The other effect, that is to say, the appearance of blue glow, and the failure of the tube temporarily, failure of the tube while the blue glow is present, is an ionization effect, and was caused in the old audion by the passing of more than a certain electron current, a certain plate circuit current at more than a certain voltage across the tube. The adjustments of both those values at which the tube would break into blue glow, being different for different tubes, and those for the same tube at different times. When the blue glow passed, the tube ordinarily ran right into saturation, if it had not already been saturated before the blue glow appeared; that is to say, all the electrons that the filament was capable of emitting under the particular conditions, were drawn to the anode during the blue glow condition. Of course, with strong ionization of that kind, the filament may have been overheated by positive bombardment, and caused in that way to give off more electrons, simply from the increased temperature, and consequently a run-away current might be produced, but that would be an effect over and above the filament battery current.

Q. 405. Now, if the tube is saturated, because of blue glow, can the tube in that condition amplify?

A. No. That is the point I was about to come to. When the tube is in this condition, it is dead; the amplifying power has gone.

Mr. Davis: I wonder if that is clear, your Honor?

The Court: It is not at the moment. I think I shall work it out.

Mr. Davis: It is simple and I think I had better stop and make it clear; on the saturation point, you are at the point of the curve where the current is independent of the voltage.

The Court: Yes.

Mr. Davis: And therefore the current is independent of the voltage on the grid and so no change of voltage on the grid would change the current in the tube

The Court: Let us see. It is independent of voltage, both of grid and filament?

Mr. Davis: Yes, sir, because all the electrons are going across that come out. I do not mean but what you might put a voltage on the grid.

The Court: I have it. I had overlooked the grid in that.

Mr. Davis: The point where your current curve is flat, and the whole theory of amplification is to have a sloped curve; is that right?

The Witness: Yes.

Q. 406. Will you please continue?

A. I think that he has distinguished between the two points, the two phenomena. I might take the transition that you mention, that is, point out that if a tube has been overloaded—perhaps that is the wrong word to use, because I have used it in the other sense—

if a tube is "adjusted," so that the voltage and the electron current, the space current, are about all it can stand without going into blue glow, then the effect of a large voltage applied to the grid will be the same as an additional voltage applied to the plate and may carry it over into the blue glow state. Of course, that is another instance where there is what the old art called a non-self-sustaining discharge, that is to say, a discharge which required the heated filament to keep current passing, but still one in which there was large ionization.

Q. 407. Now, coming back to overloading, Mr. Hogan, is it possible to overload a good high grade modern tube?

A. Yes. The capacity of the tube for handling power is not extended to the limit, so to speak, simply by making it a pure electron tube.

Q. 408. And if you have a tube which under certain circumstances in use as a telephone repeater is overloaded, and it is a good modern tube, what would you do to cure that difficulty?

A. I would put in a larger tube.

Q. 409. And by a larger tube, what do you mean there, in what respect?

A. The main criterion is filament emission, I think; of course it would require to be able to handle more power in the plate circuit, but that would come with the increased filament emission as a general rule.

Q. 410. And if you would raise the current in the tube, the possibility of current in the tube only had had what relation to the changes that were made by your telephone transmitter?

A. Until it was amply large to permit the changes I wanted.

Q. 411. Now, on the other hand, if you had a tube which was failing, a tube such as this DeForest audion, which was failing to transmit properly, not because it was overloaded, but because it broke into blue glow, and because of actions of which the blue glow was symptomatic, would you or not feel that by increasing the vacuum so that it would not break into blue glow, that would cure that difficulty?

A. No, it would not cure it, because there is a large range where blue glow does not appear in a tube running at voltages of 100 or 200 even, and below, where ionization will interfere with an increase of power capacity. Of course, in answering that, I assume that you mean a condition in which ionization was in the tube.

THE COURT: Suppose Dr. Arnold was wrong, and if I understand that question, I was wondering as it is pretty nearly time to quit, if you will tell me the pertinency of that, because it seems to me that is probably intended to meet Dr. Arnold's diagnosis of the DeForest tube, it seems to me that his diagnosis was theoretically wrong, but actually right.

MR. DAVIS: If your Honor please, I am trying to make a very specific definition. With regard to the definition of overloading, Dr. Arnold speaks of four things he had to do—better mechanical construction; of course, that is not part of the invention. Longer life of the filament; that is not any part of the invention. Overloading, curing overloading; that is not any part of the invention.

THE COURT: By "overloading," I understand you mean higher voltages on the grid?

MR. DAVIS: No, sir. I mean the failure of the tube to respond to the voice by reason of the fact that the change in current called upon is greater than the tube is capable of making.

THE COURT: And that being by reason of the higher potential or better voltages on the grid.

MR. DAVIS: I think that is true.

The Court: That is as I recall it.

Mr. Davis: You are trying to make the tube work on a bigger range than the tube is capable, and that has nothing to do with this invention absolutely. He could get rid of that by four audions in parallel or having audions with the filament spread out more and bigger plates. Now, we come to the thing which, if any, might have something to do with the invention, which is this suggestion of his with reference to blue glow, and the suggestions testified to repeatedly in all this, both in the Interference and here, which is: I said I could make a tube which would be pumped so well that it would not blue glow, or Dr. Arnold told me that he could pump a tube so well that it would not blue glow. Now, our position there in the Interference was, and it is the same here—that that is not enough; that you may exhaust a tube, so that it will not blue glow, and yet it will not be the tube of issue, and not be a satisfactory tube. That is there is a very considerable range of vacuum intermediate between the vacuum in the tube where it breaks into blue glow, and the vacuum in which that particular tube acts, that is one of the points in the Interference.

The Court: Can you help me a step further; but the higher the vacuum, the more remote you make the blue glow stage and the more remote you make that stage to which you refer, which comes before the visible blue glow stage, don't you? I thought probably they travelled together, with the ionization stage preliminary to blue glow, you might say, that it would come shortly before blue glow?

Mr. Davis: There, I think that is important, if your Honor please, and I think your Honor is wrong there. I think that is one of the vital things you have put your finger on. I had not seen it before like that. If I understand it correctly, a tube which is going to show ionization, which will interfere with space charge, it is going to show that very soon after it gets above ionization potentials. On the other hand, the tube which is going to break into blue glow, may not break into blue glow until it gets up to a high voltage, and I do not know any relation between those two things. There may be one but I do not know of it.

The Court: I had rather assumed, not knowing anything about it, that one came shortly before the other.

Mr. Davis: I think not.

The Court: Maybe that the voltage will have to be only perceptibly lower. That does not express what I mean. Suppose you get the blue glow at thirty volts. Put it that high. Then you would expect ionization at 20 or 25 or 30?

Mr. Davis: That is quite true; but on the other hand, a tube which would blue glow at 100 or 150, would be showing departures from the 3/2 power law, and the other criteria, almost from twenty volts, that is my understanding of it.

The Court: Then my guess would not have been contrary?

Q. 412. Mr. Hogan, is that substantially correct, that statement of mine?

A. Yes, I think we could work up some curves if you wanted them that would show the pressures in the DeForest audion, also the effect on the 3/2 power curve, and such a vacuum that would not give a blue glow until you got to eighty or ninety volts in a DeForest audion.

The Court: That the ionization would cause a departure from the 3/2 power curve long before you reached the blue glow?

The Witness: Yes.

Mr. Davis: Yes.

The Court: That explains a lot of things.

Mr. Davis: That is one point which I tried to make in the opening, but it seems so long ago that I can hardly remember it. The other point, the whole point is that we did not think Dr. Arnold disclosed to Dr. Jewett that he understood how to make a tube which when put on a Gaede molecular pump or any other pump, could be used practically, and hold that vacuum, because the thing, we cannot say too emphatically in this case, is that the invention is not of the vacuum.

The Court: As I understand the witness, he adds to the pumping of vacuum, a preliminary treatment of the internal walls of the tube and the middle part that is in it?

Mr. Davis: It is throwing money into a sewer to pump a vacuum in a badly prepared tube.

The Court: Now, then, have we reached the point where we can take a recess? Is the reason that the incandescent lamp, the filament of that does not emit electrons—I had better not because——

Mr. Haight: You understand that our position of course is that blue haze was simply a manifestation of ionization going on, and that made apparent to Dr. Arnold of what was happening in the tube, and the cure that he offered for the defect, which was being manifested by the blue haze was the modification of the vacuum, and that is the invention. Simply because at that particular time, the kind of filament used, and everything else, the condition that was going on was manifested by blue haze, is no reason at all for assuming that Dr. Arnold did not at that time know that ionization would take place before blue haze was manifested under certain conditions.

The Court: That I understand. If I understood the witness, he said that an incandescent lamp did not emit, the filament of the incandescent lamp did not emit?

Mr. Davis: I do not think the witness said that. I understood him to say that any emission was undesired and unutilized.

The Court: All right. It does not make any difference except I was wondering just why there had to be another electrode in the device, in order to cause the emission.

Mr. Davis: You have these two legs of the filament. First, take the two legs of the filament where you go in and go out.

The Court: Different potential?

Mr. Davis: There will be an Edison current of some magnitude.

The Court: I wonder if the electrons boil off from a hot electrode any way?

Mr. Davis: They will boil off any way, but they will probably fall back, if there is not any voltage to pull them away. My understanding is they do not go very far, if there is no voltage, but take the part that is most negative, where the negative current goes into the lamp, and there you have a hot cathode in a sense, and you remember that Dr. Langmuir spoke about the talk he had with Professor Richardson, and asked him why it was that there was not a measurable current, and Dr. Langmuir finally concluded it was space charge that held that current down.

(Whereupon, at 6 P. M., an adjournment was taken until Wednesday, November 10, 1926, at 10 o'clock A. M.)

U. S. District Court, Wilmington, Del.,
Wednesday, November 10th, 1926,
at 10 o'clock A. M.

NINETEENTH DAY.

Before:

HON. HUGH M. MORRIS,
U. S. District Judge.

Appearances: As before.

JOHN V. L. HOGAN, resumes the stand.

DIRECT EXAMINATION (Continued).

By MR. DAVIS:

Q. 413. What would be the relation, Mr. Hogan, in a tube, between the pressure at which blue glow would be visible, and the pressure at which positive ions would not substantially modify the space charge, assuming a tube to be operating at 50 volts or 100 volts, or something of that sort?

A. That matter of blue glow has two basic features that must be considered. In the first place, the blue glow depends upon the spectra of a particular gas or gases that may be within a tube at any time; and in the second place, the occurrence of a visible blue glow will depend upon both the current passing through the tube and the voltage across the tube. That is to say, on the power that produces the ionization. It is not simply a function of voltage alone. Considering the matter of the spectra, there is no connection, so far as I have been able to find out, between the visibility of a certain gas when strongly ionized by sufficient electric power, and the capability of that same gas, when ionized, to affect or neutralize a space charge. For instance, in the case of argon, we have a gas which gives relatively little light when it glows. It produces a purplish blue glow, but not very much light, largely because its ionization spectrum is, for a great part, above the visible light frequencies and in the ultra-violet rays. On the other hand, argon itself, this same gas, has got strong ionization properties, so to speak. That is, it is effective in neutralizing a space charge in a vacuum tube. Neon is a different type of gas. Neon gives a great deal of light when it is glowed. It has a characteristic reddish glow, and yet on the other hand it has much less ionization effect, and it is hard to ionize, requires a higher voltage for ionization, and I think it is of all the gases the least effective in reducing space charge.

On the matter of intensity, that is to say, the power relation, we might consider a good vacuum tube having a large current passing through it, 50 milliamperes or 100 milliamperes of electron current at a fairly good voltage, perhaps even 100 volts or so. If we leave the voltage the same and the electron current the same, and gradually increase the pressure, the gas pressure in the tube, the ionization in the tube will gradually increase. As we have all recognized, there is some measurable ionization, even below points at which ionization harmfully affects the space charge. There is no sudden beginning or sudden stoppage of ionization as a physical fact.

If the pressure in the tube then is increased, the ionization will gradually increase and there will come a time, I should say that as the ionization increased, since the electron current is constant at this assumed large value, the ratio of ionization to electron current will increase as the ionization goes up. It is that ratio which is one of the measures of the effect of ionization on the space charge. For a given tube when the ratio of the ionic current to the electronic current becomes too high there is a destruction of space charge in the tube as is evidenced by departure from the 3/2 curve.

With so much current and substantial voltages the energy, the power, in the ionization may be sufficient to produce a visible glow very soon after the percentage of ionization to electronic current has reached the point where space charge is badly affected, so that there may be little margin (and in the case of a very large voltage high current tube there may be no margin at all) between the point at which ionization hurts the space charge and the point at which visible blue glow sets in.

On the other hand, if you take a tube such as the DeForest audion or one of the small radio tubes or telephone repeaters, with a relatively small electron current, a current for instance of 100 or 200 microamperes such as is common in the old audions, put on that 50 or 100 volts, say 100 volts, and gradually increase the pressure again from a very, very low pressure on up. Here again the ionization current, the ionization in the tube, will increase gradually as the pressure of gas increases and so will the ratio between the ionization of the electron current increase.

But the ratio of the ionization current to the electron current will reach a value that affects the space charge and causes a sharp departure from the 3/2 power law above ionization long before the energy in the ionization discharge will cause a visible blue glow. That is because the electron current is so small that it is affected by a much less ionization current or energy than is necessary to give the visible glow.

There is then no direct connection between the appearance of the blue glow and the departure from the ionization free operation by space charge. In a small tube the break in the characteristic at ionization voltage, that identifies the gas effects on the space charge, will occur at pressures and low currents and lower voltages long before the voltage reaches the point where it combined with the energy flowing through the tube will make the glow visible and (as I think I said) in contrast to that, in a large power tube the blue glow may set in practically as soon, if not absolutely as soon, for all practical purposes, as the ionization becomes intense enough to offset the space charge effect of the large current.

Q. 414. In connection with Defendant's Exhibit 25, which is the Lilienfeld 1910 article, I refer you to XQ. 881, of Dr. Chaffee's cross-examination, at page 338 of the record, and his answer at page 339 and ask you what you can say as to the extent of secondary electron emission in the lower range of operation discussion by Dr. Chaffee in that answer, that is, that portion of the range which I understood him to suggest conformed to the 3/2 power law.

A. Yes, sir. That question had to do with the secondary emission of electrons in the Lilienfeld tube, and I think Dr. Chaffee agreed that in the larger energy part of the operating range of the Lilienfeld experimental tube, which is the long tube of the 1910 article and not the X-ray tube, that in the upper part of the characteristic, so to speak, the secondary emission effect became important. He thought that it might exist, as I recall the answer, below what he thought was the square law characteristic, but that it was not so prominent. In that connection I would just like to point out that the Lilienfeld tube of the 1910 article was one which had to be started, that is to say the current did not begin as soon as voltage was applied between the main anode and the cathode.

Before current flowed, electrons from the cathode came out and charged the narrow tube walls and presumably prevented the passage of current at low voltages. That condition had to be overcome, and when sufficient voltage was applied along the straight portion of the tube, as for instance, by putting a spark coil on the starting electrode, then the probability is that the electrons were caused to strike the tube walls hard enough to set up secondary emission of electrons perhaps aided in their high velocity impacts by whatever positives there were present in the tube.

That condition is what seems to result in the lower part of the Lilienfeld curves and represents the situation in the use of the tube where a voltage of 105 or something like that was measured between the sounds and representing a condition below which no current at all would flow through the tubes.

If we can assume, for instance, that the impact of the electrons on the wall when driven by sufficient electromotive force to start the discharge, will be great enough to knock two electrons out of the glass wall for each impact (and that would not have to occur for every impact, but only for some of the impacts), then the walls would have a net positive charge; that is to say, more electrons by some margin would be leaving them than would be striking them, and that would aid in neutralizing whatever negative space charge there might exist. It would co-operate with whatever positives existed in the tube, and give somewhat the same effect. Thus, the charge would be prevented from building up negatively to the extent that would again stop the current, and the rate at which that secondary emission would occur would follow some law dependent upon the secondary emission of glass under the impact of electrons. Now, if one plots Lilienfeld's data, taken between the sounds, it is found that there is no break from a 2/3 law to a 1/2 law of current variation with voltage, even when the main current is compared with the sounding potential, a sounding electrode potential; but there is a smooth curve swinging off from a very high power to a lower one; and I see no reason from Lilienfeld's data or from any further consideration that I have been able to give that tube, why secondary electron emission should not be as necessary and as prominent as far as permitting the discharge to start at the low current and voltage values, as at the high. That is to say, the discharge does not start at all until a certain condition is reached. If the negatives are there strongly on the thin tube, the discharge won't start at all, and I think one of the large factors in even the beginning of the discharge, is the secondary emission which Dr. Chaffee agreed was prominent at the latter part of the discharge, well after the current flow had begun. Also we might note in this connection, as to the bombardment of the narrow tube by the electrons, that the liberation of the discharge energy to the walls of the tube, which is characteristic of those Lilienfeld 1910 results, is a very different thing from the delivery of the energy of the discharge to the anode, and the heating of the anode as in the practical thermionic tubes.

Q. 415. Could you make a Langmuir tube, the tube of the patent in suit, by pumping a DeForest audion?

A. Not without preparation. If the anodes and glass and grid had been thoroughly prepared, a good tube could be made, but pumping alone would not cause the pressure to remain low. In fact, it would be impossible to get the pressure low by pumping alone.

Q. 416. Will you please explain why you could not make a Langmuir tube by pumping a DeForest audion?

A. Because the glass and grids and plates are not cleared of gas in the ordinary manufacture.

Q. 417. To what extent, if at all, were the methods used for cleaning up the electrodes with mercury devices, such as the Cooper Hewitt lamp, described in his patent, to which Dr. Arnold referred, and the mercury arc repeater, to which Dr. Arnold referred—to what extent, if at all, were those methods capable of being applied to the DeForest audion?

A. Well, they are so different—the conditions are so different that they are not directly applicable at all. In the mercury arc, for bombardment of the anode, one has amperes of current, watts of power, a great deal of power available to heat the electrode, and that is normal because that corresponds to the operation of the mercury arc device. On the other hand, in the audion, you are limited to certainly a few milliamperes, perhaps even less than a milliampere in many tubes, and to low voltages, the energy of which is very, very small, and the heating effects of which must therefore be very, very small.

Another difference is that in such a mercury arc tube as the Arnold repeater, there is a great deal of positive ion energy available for bombardment of cathodes, such as the metal cathodes on the sides of the tube, and there is nothing like that quantity of positives available in the audion, of course.

The DeForest audions with their tantalum filaments, were altogether too limited to permit electron bombardment of the plates to any effective extent, without either burning out or seriously affecting the filament. The little DeForest plate would take something like 50 milliamperes at 100 volts or about five watts, in order to heat it up to a red heat, say 800 degrees C., and we know that fifty milliamperes is far beyond the capacity of that sort of a tube.

Of course, the need of bombardment could be overcome by using wire anodes, such as Langmuir used in some of his early tubes and as Arnold used in the strip form in the 1915 power tube, where current could be sent through from the outside to heat the anodes, and in that way, the need of bombardment of that electrode avoided.

I spoke of red heat in connection with the audion, and perhaps I should point out that even though a device is going to be run on light power, small power, so that it really remains fairly cool in operation, nevertheless for the maintenance of a very low pressure in the device, the preparation of that tube should include the heating of the gas containing metals to a very high temperature.

The point is that the gas has got to be taken out of those electrodes during the pumping operation and preparing operation which will last only a relatively short time, a matter of minutes and it must be taken out in that short time to such an extent that in the later life or normal life of the tube it will not come out to an extent that it will bother operation.

The life of the tube, instead of being a matter of minutes will be in general a matter of hundreds or thousands of hours and consequently in the very short time of manufacture the tube must be cleared so well of gas that the long period or after life will not result in any appreciable accumulation by the slow evolution that is bound to follow if some gas is left in.

That is to say, one must for the operation of a device at rather small powers and under room temperature condition, one must in preparing it go far beyond the operation conditions and it is customary in making the little receiving tubes even to heat the plates to a bright yellow or white heat just for this reason.

On the other hand, of course, if a large device is going to be used under conditions where the anode is actually heated by the operating discharge to a high temperature so that it will glow yellow or white in use, then a statement to the effect that it is unnecessary to carry the treatment in exhaustion beyond the temperature used in operation would be correct, because the operating temperature attains the same high value that is necessary to get out all or practically all of the gas from the electrodes.

Q. 418. You spoke of this limitation of energy. What was the cathode in the mercury device?

A. A pool of mercury.

Q. 419. And was there any limitation to the current you could put through that pool?

A. No practical limitation except what the tube itself would stand in the way of heat.

Q. 420. Whereas in the case of the tube with a filamentary cathode what was the limitation?

A. The emission of the filamentary cathode itself, at temperature which would not destroy the cathode. Also of course if one attempted to attain a high emission with a good deal of gas there comes in the matter of ionization and positive bombardment which might destroy the filament.

Mr. Davis: I wanted to be sure that that was clear to your Honor.

The Court: It was made clear to me in the discussion the other night. The emission is increased by the size of the filamentary cathode?

By Mr. Davis:

Q. 421. Is that right?

A. That is correct. You can build cathodes that will give within reason whatever emission you may want.

Q. 422. Perhaps this might illustrate the point. Suppose you had the problem today of building a DeForest audion which would operate as one of the tubes in issue and were free to make little changes in the design, what is the first change you would make?

A. Of course, one of the things you do to get power today would be to increase the size of the filament. The various other changes follow from what we have discussed.

Q. 423. Referring to the data of Arnold's tube No. 20 in the condition in which it was known as 20.2 and in the condition in which it was known as 20.4, which I understand were the molecular pump exhaust of that tube, and which I believe is in Arnold's priority Exhibit 8, is or is not the information given sufficient to enable a conclusion to be drawn that this tube in these two exhausts or either of them would operate without substantial ionization?

Mr. Haight: May I ask what you are referring to in the word data?

Mr. Davis: I am referring to the data furnished by Arnold or on behalf of Arnold in the Interference with respect to that tube.

Mr. Haight: Exhibit——

Mr. Davis: It was Exhibit 8 in the Interference and which consists I understand with certain readings of current and voltage and certain E. S. curves.

Mr. Haight: That is all right with that limitation. I wanted to understand what the word data meant.

Mr. Davis: I meant the data furnished by Arnold.

Mr. Haight: You mean the data in the exhibit.

Mr. Davis: Yes, and any other data which the defendant furnished with reference to that tube.

Mr. Haight: Has there been any other furnished?

Mr. Davis: I do not know whether there has been any other data.

The Court: If the witness refers to any other data then call it to our attention.

Mr. Davis: Yes. If he is going outside of the bounds of this Exhibit 8, he should call it to our attention. You Honor may remember that Dr. Arnold said a little about this tube in his direct. A. I do not find this curve to show tube 20.2.

By Mr. Davis:

Q. 424. I am sorry but I should have referred to Priority Exhibit 19 rather than to Exhibit 8. Eighteen is the sheet and 19 is the blueprint that goes with it.

A. The curves on E. S. 86,907 summarize the data which we have with respect to this audion 20.2 and this shows two runs as to a voltage current relation of the plate discharge. The data does not give information as to what behavior this tube would have in the space charge and operating range well above ionization potentials and below saturation if it was capable of use in that range.

The curves show saturation between 20 and 30 volts. Each of the two curves has a large loop in the saturation range and those loops are indications of gas effects and not of temperature effects. They represent the sort of thing that happens when the surface of the cathode is either cleaned up or contaminated by gas effects, for example, ionization.

It is not possible so far as I know to determine the extent of the gas effects on space charge from the information that there is sufficient gas to cause some effects on emission. I see no reason from these curves to expect reproducible operation in the tube above 25 volts or so and in fact there is every reason to look for the contrary but the data are not sufficient to let me reach a positive conclusion either as to the presence of large amounts of gas or its absence.

As to 20.4 the blueprint E. S. 86,908, shows two runs in dash lines, I believe, for 20.4. They are marked molecular pump at the middle of the sheet.

Q. 425. The other two curves were on some other tube, were they, Mr. Hogan?

A. The other two curves are marked "mercury pump," and I think that had to do with the 20.3 condition of this same bulb No. 20, from the legend at the upper left-hand corner of the exhibit. Now, there was a third run covered by the data in the notebook, and I believe we have a plot of that third run.

Referring to the first, which is the curve extending highest of the dashed lines, ~~it~~ is clear that the operation was irreproducible above 40 volts; that is to say, the two curves depart and do not return together until approximately 40 volts. The second run showed a much smaller loop, but the third run, which was not plotted on E. S. 86,908, shows at a somewhat higher filament current, a very much more rapid increase of current with voltage, and the appearance of a dim haze, together with an increase of current running off the scale of the plot.

This pair of curves on the blueprint E. S. 86,908 shows the same gas loops at the saturation point, and in the case of 20.4 on the third run, we have a blue haze shown at the region corresponding to 90 volts or so. I think that these records are not proof that the tubes were even substantially free of gas ionization; that is to say, I think the data are not sufficiently complete to let me reach that conclusion as a scientific matter. On the other hand, I could tell definitely what these tubes were if we had more performance information concerning them. Points that are useful in connection with the complete study of any vacuum tube from this angle, include matters not given here, such as to which terminal of the filament the plate voltage was measured; how the grid in the tube was connected during the run, or whether it was not connected to any electrode; what the grid current amounted to during the run, if the set-up did show a connection and grid current; what the effect of the filament drop was as could be determined by using the rotating commutator; what was the effect produced on the general characteristic by contact potential between the filament and grid, for instance, if any contact potential existed, as it often does, and whether that contact potential remained constant; what the law of discharge was below ionization voltages, that could be had from current voltage data taken in the absence of these other complicating factors at low voltages, and would give a clue to the performance of the tube before ionization could have set in; what amplification constant the tube had, and finally, so that saturation effects could be eliminated from consideration, a set of data for several operating temperatures.

Very often that kind of information will give a definite idea of the performance of a tube which would not be suspected from a run taken at a single temperature. For example, in connection with this 20.4, when the filament current was increased from the .64 amperes used on the second run, where it showed fair reproducibility up to about 100 volts—good reproducibility in so far as this curve indicates—as soon as the filament current was increased to .69 amperes, an increase of .05, 1/20 of an ampere through the filament, the blue haze, and so-called run-away condition of the third run set in.

Q. 426. I ask the same question about Dr. Arnold's tubes identified in the Interference record as A-3, B-3 and B=19 (?). That last was the way the tube was referred to in the notes, B=19 (?).

A. Audions A and B, which I believe are the A-3, and B-3, to which you refer, are represented on this same blueprint E. S. 86,907. In the two dashed curves A at the bottom and B through the middle of the sheet. These data are inconclusive on the points as to which you inquire, because we do not know how much the effects occurring below ionization cause the steep slope in the curve, and carry it above, and are projected above ionization voltages. Measurements below ionization potentials here are absent or uncertain. Ordinarily, a break to a steep slope around ionization potential would prove substantial gas ionization; but here the break, if it actually occurs, is masked by reason of undetermined factors, or at least of unknown factors below ionization. For example, contact potential and filament drop, as affected by the amplification constant; and consequently I think the data is inconclusive with respect to A-3 and B-3. Now as to B-1[illegible]——

Q. 427. Just a moment. Let me see that curve. May I ask a moment to be sure I am getting those curves right, if your Honor please?

A. You will have to find the curve.

Mr. Davis: I think, if your Honor please, the witness has been talking about A on E. S. 86,907. Perhaps my question was ambiguous, but I was referring to another exhaust in the same tube.

The Witness: I might point out that the A curve shows on this sketch a great departure on the rising and falling, even below actual saturation, and that that is ordinarily an evidence of gas, and probably is in this case, and that a similar departure above sixty volts is shown in the B curve, that irreproducibility extending well down below the final saturation point.

Q. 428. Now, if you will take the curve of A-3 and B-3 as distinguished from A.

Mr. Davis: I would like to hand to the witness the plot made in the Interference which appear in some of our briefs, and I hand the witness the data from which the plots were made which is on pages 114 and 115 of the Pierce notebook which is Arnold's Priority Exhibit 8, the plot which I referred to is on page 2078 of the priority record, but it was a plot made by or on behalf of Dr. Langmuir instead of being made by Arnold

I am wrong in saying that it was a plot made in the brief. It is a plot made in the record.

A. This sheet, referring to the same tubes on the exhaust marked 3 which is on page 2078 of the Interference record, shows these same departures or loops on the saturation part of the curve and extending down somewhat below and into a transition portion and also shows the steep slopes which are, as I said, in general, characteristic of gas ionization when they appear above the ionization potentials.

I do not know how such steep slopes could be had in a tube which did not have gas ionization but I cannot make the complete comparison without further information as to the tube below ionization potentials and the effects of filament drop, contact potential and so on.

In any event, the data would have to be further explained if they were to lead to any other scientific conclusion than that there was substantial gas present and gas in sufficient amount to cause ionization that would interfere with space charge operation.

Q. 429. Have you dealt with the curve B-19 or not? It is on E. S. 86,907.

A. I think I did. Yes, I am quite sure I covered that. It is the one which is in the middle of 86,907 in dash form. Have we not a log plot of that particular curve?

Q. 430. Just look at the data of that B-19 and compare it with the plot and see if you notice any discrepancy in the lower part of the curve or points omitted in the consideration. That data is on page 107.

A. To answer your question I will have to check each of these points.

Mr. Davis: I thought the witness had done so and we will postpone this question until he has had an opportunity to do so.

Q. 431. It has been testified when the Arnold tubes went into operation in Philadelphia in the fall of 1913, the energy was limited to four milliwatts and we may assume that to be the testimony. What if anything in your judgment made that limitation necessary?

A. I think it has also been testified that the difficulty that caused limitation of the energy in the Philadelphia work was the singing of the repeater circuits using the tubes and that is to my mind perfectly reasonable. The singing in balanced telephone repeaters will easily occur, and will be hard to control, if the repeater tubes or the other repeater elements used are irregular in their operation.

If one balanced for one condition and the tube constants changed for any cause it may be necessary to rebalance and consequently an unstable tube will give a great deal of trouble.

These audions could be made stable, or could be made of increased stability, at least, by reducing the voltage applied to them and that of course at the same time reduces the amplifying power of the tubes and the two things together aid in attaining the balance.

A steady tube of higher amplification than the Kendall report shows was used, would be perfectly capable of balancing.

Q. 432. Arnold's Exhibit 23 on Priority consists of a report or memorandum of Kendall dated October 1, 1913, on the use of the audion as a telephone repeater. That report speaks of a resistance which may be used in series with the audion, when used for that purpose, and speaks of a current of about 500 microamperes or half a milliampere and the resistance of 10,000 to 50,000 ohms. It also speaks of a B-battery from thirty to fifty volts. Please assume that the larger resistance, 50,000 ohms, is to be used with the larger B-battery voltage, fifty volts, and tell me what the voltage is on the terminals of the tube on that assumption?

A. That is a simple computation based on subtracting the voltage drop in the series resistance, caused by the current flowing through it, from the battery voltage. The resistance is 50,000 ohms and the current is five-tenths of a milliampere so that the voltage drop in the resistance is 50,000 times .0005 in volts or 25 volts. Therefore, the resistance reduces the drop of 50 volts from the battery to 50 minus 25 which equals 25 and leaves 25 volts at that current, applied to the audion.

Q. 433. That computation is based on ohms law?

A. Yes.

Q. 434. Which is C is equal to E over R?

A. Yes, and in this form is the voltage equals the resistance times the current flowing through it.

Q. 435. E equals C. R.?

A. Yes.

Q. 436. And that is true of any part of a circuit?

A. Yes, for instantaneous values anywhere.

Q. 437. Please make the assumption that the lower resistance of 10,000 ohms is to be used with the lower B-battery voltage mentioned which is 30 and tell me what the voltage would be on the terminals of the tubes?

A. In this case we multiply the resistance of 10,000 by the same current, .0005 ampere, that is 500 microamperes, giving a product of five volts and we subtract the product thus obtained, five volts, from the battery voltage 30, and get the difference of 25 volts available from the battery after passing through the resistance for application to the audion.

Q. 438. In the blueprint attached to this report, for example, blueprint E. S. 123,785-L, do you see anything representing that resistance?

A. Yes, the element D appears in a one-way repeater circuit, arrangement 1, and again in the one-way repeater circuit, arrangement 2.

Q. 439. And what is this thing marked E?

A. E is a condenser shunted across that resistance, the resistance being in series with the plate circuit.

Q. 440. Now, will you please compare that resistance and its connections with the resistance shown in Arnold's Patent 1,114,845 on page 2346 of the Interference record?

A. The diagram of this patent 1,114,845 is on page 2347 and shows a resistance element 8, shunted by a condenser 9, the two being directly in series in the plate circuit. In the patent the resistance and condenser are on the plate side of the primary coil of the transformer marked 6, whereas in the blueprint accompanying the report they are on the battery side of the transformer primary winding, but this makes no difference in practical use.

Q. 441. Will you now please analyze the tests and curves testified to by Dr. Kelly in this suit, first certain curves on tubes said to be good tubes and said to show laws other than 3/2 power law and second on tubes said to be tubes of relative poor vacuum and said to show laws like the 3/2 power law?

Mr. Davis: Before the witness answers this question I will offer in evidence Plaintiff's Exhibit D for identification being certain data supplied by Dr. Kelly at plaintiff's request.

(Received in evidence and marked "Plaintiff's Exhibit No. 185." *See Volume IV, Plaintiff's Exhibits, page 167.*)

Mr. Richmond: I object to the question as entirely too general, giving the witness unrestricted permission to review a large field of testimony. It seems to me the question ought to be more specific and directed to particular matters.

The Court: Suppose I take your objection under advisement and as the witness goes afield from it, if you will call my attention to it we will see whether a number of questions will have to be put.

A. If we take up first Exhibit 48 which represents some data on audion 64, later No. 91, I believe that Dr. Kelly said of this that the plate of Exhibit 48 showed the tube to be a high vacuum or ionization free tube because the 4/9 plot of the current with respect to the voltage was a straight line.

Mr. Richmond: I do not understand that Dr. Kelly said that.

The Court: You think the witness is setting up a straw man to knock down instead of the real testimony. That is vital in this case. Then if you will, will you make your questions specific, Mr. Davis?

Mr. Davis: Then we will see what Dr. Kelly did say. I will withdraw the question.

By **Mr. Davis:**

Q. 442. I ask you to take up such of Dr. Kelly's exhibits as you think desirable to take up and discuss any scientific facts that you want to with respect to those exhibits?

Mr. Richmond: I object, your Honor.

The Court: Can you not narrow the latter part of that, Mr. Davis? It seems to me it is pretty broad. It is passing the disposal of the answer over to the discretion of the witness.

Q. 443. Will you please take up, Mr. Hogan, the exhibits introduced by Dr. Kelly such as you deem important and discuss scientific facts in connection with those exhibits relative to the matters in controversy in this case?

Mr. Richmond: I object.

The Court: I think your objection is well taken and suppose we take our short recess now because I think the questions should be limited so that I may determine from the question rather than from the answer as to the field which the witness is called upon to cover.

We will take our morning recess.

(After a short recess.)

By Mr. Davis:

Q. 444. In one of your answers this morning you spoke of a number of pieces of information which were or might be useful in connection with the study of the curves of the performance of certain tubes. I want to ask you whether or not it is your opinion that all of this data is necessary with respect to a particular tube?

A. No, of course not. In many cases a single characteristic will show all that one needs to know about the tube. In other cases a single characteristic may leave one in doubt and some additional information will be helpful in that event.

Q. 445. Coming back to this matter of Dr. Kelly's data, will you please refer to Exhibit 48, one of Dr. Kelly's curves, and tell me whether or not the data on that curve, and of course any other data which Dr. Kelly furnished, is sufficient to show the character of the tube or the discharge in the tube?

A. This set of readings (in the direct form, that is to say, plate volts against the micro-amperes in the plate discharge) has been plotted on logarithmic paper from the numerical information given us by Dr. Kelly and I think now introduced as one of plaintiff's exhibits.

A tube in which there is no substantial ionization effect on the space charge operating characteristic in general shows a gradual attainment of the 3/2 power slope as the voltage applied to the tube increases for the reason that the modifying factors or effects of contact potential and of filament voltage drop and so on, as they are reflected in the plate circuit by the amplification constant, become as a rule less and less important as the voltage becomes higher.

For that reason the Langmuir tubes in general show a slope starting at a rate somewhat higher than the 1.5 or 3/2 power and below the 3/2 power line and then slope into the 3/2 power line as the voltage is increased.

This tube 64 shows an opposite characteristic, that is to say, although there are no data given below twenty volts when one plots what figures we have logarithmically, it is seen that the curve bends upward and away from the 3/2 power line of less slope as the voltage increases.

Saturation will, of course, tend to pull down the slope through a transition range, but in this case I think saturation was higher.

That increasing slope indicates the presence of gas in the tube. On the other hand, the ionization measurements calibrated by Dr. Kelly's duplicate tube gave a pressure of only .015 microns and that to my mind should show on the log plot a good ionization free operation. I cannot explain that inconsistency on the information that I have.

The tube is somewhat blackened, the inside of the wall of the bulb is somewhat blackened and a good deal of the filament material is gone so that it is entirely probable, almost certain in fact, that evaporation clean-up in the tube may have improved the vacuum during the period that the filament life became exhausted; that is to say, we cannot be certain from a pressure measurement taken now what the pressure of the tube was in its normal condition or its original condition. I think it is entirely probable that that destruction of the filament——

Mr. Richmond: I object to the conjecture, your Honor.

Mr. Davis: It seems to me——

The Witness: My experience with tubes of this kind—is that a proper approach, your Honor?

The Court: I think Mr. Davis wanted to say something.

Mr. Davis: I wanted to suggest that a man who has had many years' work in this field, as Mr. Hogan has had, and he finds a phenomenon which is found here, that the tube is practically destroyed, all Dr. Kelly said so far as the utility is concerned and the fact that the Wehnelt cathode materials comes off and as an expert he is entitled to state what conclusions he draws from that.

Mr. Richmond: I should think so if there was a degree of certainty attached to it but this is a conjecture as to what he thinks is probable.

The Court: Of course, we deal in probabilities in law as we deal with probabilities ordinarily. The witness used the words "I think the probabilities are," and "probably" in his interpretation and it is a feeling of judgment and how strong that judgment or probability is I think is a question for you to determine on cross-examination. You may proceed, Mr. Hogan.

A. (Continued): All I want to say on that point is that clean-up from a filament that has been destroyed in this way might have been accompanied by a knocking on of filament particles by positive ionization in the tube, that is to say, the filament may have been destroyed not only by temperature but by bombardment.

THE COURT: I think in that part of the witness's answer he has gone into the field that is objectionable where he said it might have been. When he puts it into the realm of possibilities we are not interested in that.

MR. DAVIS: I have no objection to that being stricken.

THE COURT: Yes, I think that should go out.

MR. DAVIS: I will ask a question to bring out that point.

By MR. DAVIS:

Q. 446. If a tube with a Wehnelt cathode such as this tube 64 was originally is operated with gas in the tube, what if anything is the effect of that gas on the Wehnelt cathode?

A. The effect of the gas may be or will be to change the emission or to bombard the filament mechanically, the two things may go together, and depending upon the extent of the bombardment and the kind of gas and the kind of filament emission will be changed or even the filament will be destroyed.

Q. 447. And when you say the filament will be destroyed, will you please give us a little more of the mechanism of that action of destruction?

A. Sufficient ion bombardment will mechanically dislodge particles of the filament material.

Q. 448. Have you finished your answer with respect to that tube 64?

A. I think so.

Q. 449. Will you now please refer to Defendant's Exhibit 49, which I think has to do with defendant's tube 102? In your opinion as an expert is the law of the discharge of that tube or not the 4/9 power law?

A. To analyze this tube I have had the data which Dr. Kelly gave us plotted in logarithmic form.

Mr. Davis: May I interrupt the witness to offer that last plot before we get so far that we will lose it? I offer in evidence the logarithmic plot referred to by the witness in his discussion of Defendant's Exhibit 48.

(Received in evidence and marked "Plaintiff's Exhibit No. 186." *See Volume IV, Plaintiff's Exhibits, page 175.*)

By Mr. Davis:

Q. 450. Will you please continue your answer, Mr. Hogan?

A. This is standard 102-D vacuum tube and is generally recognized as a good electron tube.

Q. 451. That is one of the Western Electric tubes?

A. That is correct, yes.

Q. 452. And it has a Wehnelt cathode?

A. Yes. The logarithmic plot of the data shows the decreasing slope approaching the 3/2 power as the voltage is increased to fifty and 100 and to the final reading of 130. The 3/2 slope being indicated on this sketch by a straight dash line.

The slope of one and a half or three-halves is not quite attained at the highest voltage given, 130. I think that higher voltage readings would not have made any break in the other direction, but that the characteristic would have come still more closely on the 3/2 slope. This particular tube, the 102-D, is a tube with a very high amplification constant, an amplification constant of 30, I believe, is the rating. This has something like five times higher than the normal radio or ordinary amplifying tube has. Of course, that high amplification constant exaggerates the effects of contact potential and filament drop that in a tube with a lower amplification constant would not affect the 3/2 characteristic the logarithmic plot characteristic to such high voltage.

I think that while the straight line through the 4/9 current voltage relation of Dr. Kelly's Exhibit 49 shows a conformity of the values observed with that function, the reason that that occurs is because of these steepening effects of filament drop and contact potential as carried into the higher voltages by the amplification constant, and I feel quite confident from my own experience with other tubes that have shown these similar effects, if one took out the contact potential effect and the filament effect by using an opposing battery for the first and a rotating commutator for the second that this tube would show a very different relation with respect to the 4/9 power.

In other words, while the 4/9 approximates the unmodified readings, the readings taken under these conditions, the true law of the discharge in the absence of those factors would not be the figure of that sort but the discharge would approximate closely the 3/2 power toward which the curve is approaching.

In that connection I would like to refer——

Mr. Davis: I will offer that logarithmic plot referred to by the witness in evidence in his last answer.

(Received in evidence and marked "Plaintiff's Exhibit No. 187." *See. Volume IV, Plaintiff's Exhibits, page 176.*)

A. (Continued.) In this connection I would like to refer to a logarithmic plot of the characteristic of a small receiving tube that was introduced as Arnold Exhibit 79 to in the Interference record and which is reproduced at page 563 of that transcript.

This is testified to by Van der Bijl at the top of page 652 in which he says that this is the logarithmic plot of the characteristics shown in Figure 44 which is printed on page 651 and refers to the same small receiving tube.

His testimony continues: "The slope of this line for the operating range of voltage is about three." On the curve it is shown as 2.9. "This high value for the slope is due to the contact potential difference between the filament and the grid which manifests itself much more strongly in the tubes operating at low voltages than in high voltage tubes. When this is corrected for we get the characteristics shown in Figure 46," which appears on straight paper as Exhibit 80, page 654—"and the log plot of this characteristic is shown in Figure 47," which is reproduced on page 655.

Van der Bijl says with respect to that, the slope of this line for the operating range of voltage is 2, in other words, he reduces the slope from about 3 to about 2 by what he calls a correction for the contact potential difference which we have been discussing this morning.

In connection with that curve at page 655 I would like to point out that the agreement with the line of slope 2 is not good, the lower and the higher points are below the line and the middle points are above the line, so that a careful curve drawn through these points will be a curving line and not a straight line. That simply indicates that the contact potential correction of 8 was not enough in this instance and so I have had plotted another curve from these same data with a correcting contact potential of 12.5 as it applies to the plate voltage, the anode voltage.

This curve is marked log plot of characteristic of small receiving tube corrected for contact potential difference by 12.5 instead of the 8 volts used by Van der Bijl.

Mr. Haight: May I interrupt just a moment? Did I gather that the witness is now using some testimony of Dr. Van der Bijl to support his contention regarding some of the work of Dr. Kelly or some of Dr. Kelly's testimony? If he is I submit that it is improper.

(Discussion.)

The Court: The portion of the answer with respect to the Van der Bijl reference is stricken out.

Mr. Davis: It means that I will have to do the same thing over again.

The Court: You may but it will get opinion rather than argument. I think the objection is a proper one and it is sustained.

By Mr. Davis:

Q. 453. Please refer to the transcript of the Interference record at page 653. There you will find a curve plotted or produced in behalf of Arnold in the testimony of his witness Van der Bijl. The witness Van der Bijl says:

> "The slope of this line over the operating range of voltage is about 3. On the plot itself the slope of the line is 2.9."

That is at page 652. Mr. Van der Bijl has testified on the same page as to the replotting of that curve, making a certain assumption, which assumption is that you may correct for the contact potential of that tube by assuming eight volts contact potential. He recalculates, as I understand it, and gets the curves on page 654 and particularly the logarithmic curve at 655. I will ask you if you have made a similar recalculation and replot of the data referred to but with a different assumption as to contact potential?

A. In the first place, Mr. Davis, the contact potential itself is not eight volts. It does not run as high as that, but the effect of that——

Q. 454. When I said contact potential I meant contact potential multiplied by amplifying power of the tube.

A. Or whatever other constant is involved.

Q. 455. Yes.

A. I have had a curve plotted with a correction at 12.5 volts instead of 8 volts and that shows a straight line from the lowest reading of 7 volts to the highest reading of 43 volts, subject not to a systematic variation but to slight fluctuations causable by difficulties of reading instruments.

Q. 456. And the slope of that line is what?

A. 3/2.

MR. RICHMOND: Your Honor, you will tell me whether my point goes to the weight of the evidence or makes a valid objection, but it seems to me that this was a matter of cross examination of Van der Bijl and it is quite improper at this stage to attack his testimony in this way.

MR. DAVIS: Cross-examination of Van der Bijl?

MR. RICHMOND: Yes.

MR. DAVIS: In the old case?

MR. RICHMOND: Yes.

THE COURT: I think this is admissible, Mr. Richmond. It comes close to the border line and for that reason I will admit it.

MR. DAVIS: I offer in evidence the plot referred to by the witness.

(Received in evidence and marked "Plaintiff's Exhibit No. 188." *See Volume IV, Plaintiff's Exhibits, page 177.)*

By MR. DAVIS:

Q. 457. Have you finished your answer with respect to that tube, Mr. Hogan?

A. Yes, I suppose that you do not want any reference to this type G tube of Van der Bijl.

THE COURT: What page is the Van der Bijl plot?

MR. RICHMOND: 653, as I understand. Let Mr. Davis check it up.

MR. DAVIS: 653 in the first page to it, yes.

By Mr. Davis:

Q. 458. Did you in a similar way replot Mr. Van der Bijl's curves at pages 651–652 of the record, Mr. Hogan?

A. I have here both 2/3 power of the current against grid volts and plate volts, and also a logarithmic plot of the tube, the type G power tube referred to in the Van der Bijl diagrams on pages 661 and 662, Arnold Exhibits 87 and 88, the two page-references being to the Interference record, showing a good agreement with the 3/2 power law for a tube of this sort in which the voltage readings run up into the hundreds of volts, in fact, to one thousand volts, on the 2/3 power plot.

The 2/3 power of the current plotted against the anode voltages give a good straight line both for the grid volts equals zero, and for the grid volts equal minus 35 and the 3/2 power plot showing anode corrections of 55 and 475, both giving good 3/2 power agreement.

Mr. Davis: I offer in evidence the two plots referred to by the witness, consisting of two sheets of cross section paper.

(Received in evidence and marked "Plaintiff's Exhibits 189 and 189-A." *See Volume IV, Plaintiff's Exhibits, pages 178 and 179.*)

By Mr. Davis:

Q. 459. Does that finish the discussion of that tube?

A. Yes.

Q. 460. Now, will you please in the same way discuss Defendant's Exhibit 50, which is a plot of the tube 201-A and tell me whether or not the 4/9 power is the law of the discharge of that tube?

A. This 201-A tube is a plaintiff's tube and I have data on that extending outside of the range of 25 volts to 80 volts which were used in Dr. Kelly's plot, Exhibit

No. 30. That plot was made without correction either for contact potential or filament drop. I have here a logarithmic plot from data on a 201-A tube taken in three ways, first according to curve A without rotating commutator and without compensation for grid contact potential.

That curve shows a rather steep slope. Then curve B is taken with the rotating commutator which eliminates the filament drop effect and that has caused the curve for the same tube to show higher current for given voltages and to show a bend. When a negative voltage of one volt was applied to the grid to compensate for the contact potential and the rotating commutator was used, curve C was had which is shown repeated at the right-hand side of the curve and which shows a good 3/2 power agreement from 10 volts to 140 volts, thus indicating the law of the discharge in the tube as of the 3/2 power when disturbing factors are eliminated.

This is marked UX-201-A and I think your Honor understands that the only difference between UX tubes and UV tubes which have been referred to in connection with the 201 tubes is that the UV has the old style base with the short prongs but the tubes are the same.

Mr. Davis: I offer in evidence the plot referred to by the witness.

(Received in evidence and marked "Plaintiff's Exhibit No. 190." *See Volume IV, Plaintiff's Exhibits, page 180.*)

Q. 461. Now, refer please to Defendant's Exhibit No. 52, and will you discuss that from the same standpoint?

A. Exhibit No. 52 shows 4/9 current plot of this tube 100, later 105, Arnold priority Exhibit No. 32, and a similar 4/9 current power plot of the tube L-399, which is the so-called approximate duplicate of that tube No. 100.

Q. 462. Then I will ask you, Mr. Hogan, perhaps my question was not quite definite, to add to your answer as to whether the data given is sufficient to judge the character of the tube?

A. Exhibit No. 61 is a 2/3 power plot of these same tubes. The 105 tube is the only one I am considering, and for that we have no data below 30 volts where Dr. Kelly said, I believe, that no current passed through the plate circuit at voltages lower than 30. I do not understand that.

Mr. Richmond: Your Honor, must I wait until cross-examination to challenge the accuracy of the statement?

The Court: No, because that may mislead any Court if it is not accurate. If there is inaccuracy in the statement, then you may object.

Mr. Richmond: Then I object. The statement does not correctly represent the witness's testimony.

A. (Continued.) Perhaps, your Honor, I was wrong in saying that Dr. Kelly made that statement. The point was that the data given us showed no current for 20 volts and a measured value of current at 30 volts, and that was expressed to me as the statement that there was no current flowing below 30 volts. I do not know whether that is a proper statement or not, but we have no data below 30 volts.

Mr. Richmond: I think that is all right. I do not challenge it now, but I will look it up for cross-examination.

A. (Continued.) Starting then, I have no data below 30 volts, and a 20-volt reading in the data sheet showed no current reading; this is the thing which I find hard to understand. I do not know why a tube of the sort we are talking about here should not show a substantial current flow at 20 anode volts with a reasonable filament temperature.

I have had the data replotted on a logarithmic sheet and would point out that the slope of the line showing the increase of current against voltage is something like the eighth power from 30 to 40 volts; that is to say, is a very steep rise and that from that point on, the slope is about 3.9 for the next few readings.

I think that this was a tube having high amplification constant which would accentuate the effects of filament drop and of contact potential and also some of its peculiarities might be explained by the position of the filament with respect to the rather small and incompletely shielding grid.

In any event, I think the information is not sufficient to show whether the tube has a high slope due to gas or due to some other complicating factor at the higher voltages, and I would hesitate to draw a positive conclusion though I believe that the performance is unusual with respect to a normal "hard" tube in a good many particulars.

Q. 463. Will you now please refer to Defendant's Exhibits Nos. 53, 54 and 54-A, which have to do, as I understand it, with tube 9.111, and say whether or not the data given is sufficient to show the characteristics of that tube?

Mr. Davis: I would like to offer in evidence the plot referred to by the witness in the last answer.

(Received in evidence and marked "Plaintiff's Exhibit No. 191." *See Volume IV, Plaintiff's Exhibits, page 187.*)

A. There were three exhibits introduced in connection with this tube A-9.111. Exhibit No. 53 and 54-A are marked A-9.11, and Exhibit No. 54 is marked A-9.111, but I understand that these were for the same tube and that discrepancy in the marking did not appear to me until just now. Perhaps that ought to be solved right now. I had thought that this was the tube which has a logarithmic plot reproduced as Langmuir Priority Exhibit H at page 2085 of the Interference record.

MR. DAVIS: It is my impression that that was called to Dr. Kelly's attention during his examination that is, Exhibit 53 is headed Arnold A-9.11 but on the curve itself it says 9.111, and Dr. Kelly stated on cross-examination that the lines were for the same tube, that is, the one that has three ones after the nine.

A. (Continuing.) And that would apply also to 54-A, in which the curve is not marked.

By MR. DAVIS:

Q. 464. You may proceed on that assumption, and if it is wrong, the defendants will correct it?

A. That is supposed to be a correction of the lowest line of Exhibit No. 54, and I think it would be the same tube.

Q. 465. There is no tube 9.11 in the case, so far as I know.

A. Then we may take Exhibit No. 53 as comparing this tube A-9.111 with tube No. 100, later 105, on a 4/9 power current plot, and Exhibit 54 as showing four curves of the tube A-9.111 for four values of grid voltage, the plate current being plotted against the plate potential after the plate current is raised to the 4/9 power. And also Exhibit 54-A is the correction of the lowest line in Exhibit 54 after the error in plotting the upper three points was discovered.

The three plots at the top of Exhibit 54 are for positive values of grid potential 1½ volts, 2.6 volts and 4 volts. And it seems to me that unless the grid current for these positive voltages is either included in the current reading or is shown to be negligible that the three curves based on that data would not be conclusive.

As to the lowest plot, which is taken with a zero grid potential, and that I assume as grid connected to the negative leg of the filament and not the positive connection which Majorana called the neutral potential, then the grid current need not be considered as a general rule.

There was some difficulty with respect to the lowest point, the twenty-seven-volt point on the curves of Exhibit 54 and 54-A. That point is shown in a logarithmic plot at page 2085 of the Interference record and a curve is drawn through the various readings and compared to a theoretical 3/2 power straight line drawn through the lowermost point. If that point is a good point, that is to say, if it represents a real measurement as we have always assumed up to now with respect to the—perhaps I should not say that, but if that represents a good measurement then the curve shows a sharp gas effect and if it is an error in measurement, I think it would be very difficult to say what the curve shows.

Again we have a case of steep slope which would indicate gas, but the break would not be given because with that point omitted, we have no data below forty-nine volts, which is well above ionization potential.

As to the way in which the 4/9 plot may be used to represent a straight line, I think a comparison of the upper seven points, near which or through which the lines are drawn on both Exhibit 54 and 54-A, will show that the straightness is not a very exact test for even when the three highest points were moved upward to a fairly substantial amount, one large space on the paper, it was still possible to draw a straight line that looked fairly representative of all the points though of course the slope on that line is quite different from the slope of the straight line drawn through the points as originally plotted and which reach the upper intercept 25.8, and which I have re-plotted for comparing in red ink on a copy of 54-A.

Incidentally, on the original basis, the slope of the line through the lowest readings for grid voltage zero, was practically parallel to the three lines at the upper readings, but when the lower line is corrected, it is no longer parallel as it should be if the upper reading were to be used, and I think that is a further indication that they can not be relied upon.

Mr. Davis: I offer in evidence the plot referred to by the witness, being a copy of Defendant's Exhibit No. 54-A with certain additional lines drawn thereon.

(Received in evidence and marked "Plaintiff's Exhibit No. 192." *See Volume IV, Plaintiff's Exhibits, page 182."*)

By Mr. Davis:

Q. 466. Now, will you please refer to Defendant's Exhibit No. 57, which is blue print of a Kelly diagram for helium filled tube, the tube itself being in evidence as Defendant's Exhibit No. 56? Will you tell us what technical conclusions you draw as to the nature of the discharge and the effect of the helium pressure said to be present in that tube on the discharge?

A. Here we have measurement data taken down to ten volts plate, and running up to 120 volts with corresponding plate currents, and also a converted plot on the same exhibit, giving the 2/3 power relation of the currents down to lower voltages, the only break being at very low voltages where a failure to correct for contact potential or filament drop emission caused the deviation.

This tube had from 3 to 3.9 microns of helium gas in it, and also had a very low amplification constant, the value being given as from 2 to 2.5. The grid was extremely close to the plate, the separation being only 8/10 of a millimeter, or something between 1/3 and ½ the normal grid-plate spacing.

Moreover, the grid is shown on Exhibit No. 57 to have been at zero potential, that is to say, at negative filament potential, so that the plate drop was developed in the tube only across that 8/10 millimeter space, the full voltage being there most effective.

Helium has a very high ionization potential, 25.6 volts, I think, and in helium the probability of ionization at any given pressure is less than that of any other gas, so that with helium and these pressures and these spacings, that is to say, the extremely small distance for the electrons to go and the consequent extremely small probability of ionization in travelling that distance under the accelerating voltage, we get what is really a good Langmuir tube, a tube that is good in all respects as far as can be judged from these data.

It is a very interesting example of how the pressure itself at which freedom from ionization is sufficient to prevent Interference with space charge effects, may be varied, dependent upon the content of the tube and the geometric arrangement of the electrodes, even to pressures that would be altogether too high if used with some other kind of gas, or in a tube of some other construction.

Of course, in that connection I should note that the gassy readings, if one wishes to call them that, that is to say, the readings of voltage and current in this tube, even at 3 or more, 3.9 microns, were reproducible, and that that was so because there was no ionization of substantial amount, and because the pressure stayed constant for the reason that the tube had been previously cleaned up, it had been given a Langmuir treatment, as I think it stated on the cross-examination. I think that is all.

Q. 467. Will you now refer, please, to the Defendant's Exhibits Nos. 58, 58-A and 58 B, which had to do with a tube testified to by Dr. Kelly, at which various pressures of nitrogen were introduced, and state what effect this nitrogen had on the nature of the discharge?

A. Exhibit No. 58 is of this tube No. 7510 at a nitrogen pressure of .02 microns. Exhibit No. 58-A is a similar 2/3 current plot for the same tube with a pressure of .64 microns and Exhibit No. 58-B is a similar plot, the pressure having been increased to 1.2 microns. So far as I can judge from the data available, this tube operated as a good space discharge or Langmuir tube at this lowest pressure of 2/100 microns.

A logarithmic plot of the data given for that pressure of .02 microns shows the effect which I have discussed in connection with some of the other tubes, namely, the decreasing tendency from a rather steep slope toward or to a 3/2 power slope, which is in general characteristic of a good tube. Here the last two points which are at 110 and 120 volts, are actually on the 3/2 power curve, and I believe that if higher voltage readings had been given the characteristic of the tube would have continued on that slope, the steepening effect having become inconsiderable at that potential for those conditions.

At the higher pressures the curve does not slope over to the 3/2 power line at the voltages given and so far as I can judge would not have reached the 3/2 power until a transition to saturation had set in. The increased current corresponding to the pressure of 1.2 microns is shown in the upper curve on this same logarithmic replot. I have not shown the intermediate curve for the intermediate pressure, simply because the points would be confused, but I think it is clear that the slope of the last data given is considerably steeper than the 3/2 power, and that while there is a general reduction in slope, there is no way to tell how much of that is produced by a transition, perhaps a long transition into a saturation region.

Here again we have readings of voltage and current which I understand and believe were reproducible just as in the case of the helium filled tube. I am not certain that it was testified to that they were reproducible, but I assume they were, because definite characteristics were given without any evidence to the contrary, and that would follow from the fact that this 7510 tube, like the other tube, was well cleaned, given a Langmuir evacuation before gas was put in, and from the further fact with relation to 7510 that the pressure was held constant by keeping the tube on the pump during the time that these measurements were made.

Mr. Davis: The curve sheet referred to by the witness in his last answer is offered in evidence.

(Received in evidence and marked "Plaintiff's Exhibit No. 193." *See Volume IV, Plaintiff's Exhibits, page 183.)*

Mr. Richmond: The very last statement of the witness, I think is contrary to the evidence, and so I object to that about the connection being maintained to the pump. I think the testimony will show that it was trapped off.

The Witness: In any event, my understanding as to the clean-up is correct, is it not, that is, the tubes were given a good clean-up?

Mr. Richmond: Yes, that appears.

The Witness: But I was wrong in believing that it was open to the pump?

Mr. Richmond: Yes.

The Witness: Then I will not stand on that statement.

THE COURT: Then suppose that be stricken out, the last statement, and the witness bases his conclusion on the corrected understanding.

MR. DAVIS: Yes.

THE WITNESS: The only point is that with high gas pressures in a discharge, one could hardly expect constancy, one could not expect it at all, unless the tube had been well cleaned out so that the pressure could be held uniform, whatever pressure the tube is made to operate at.

By MR. DAVIS:

Q. 468. I understand, Mr. Hogan, that you wish to make a correction to your answer that you made on page 2937. I ask you to make any statement you care to.

A. This is question 394 asked of me by Mr. Davis and saying according to the report:

> "I will ask you as a person skilled in the art and knowing the use of the terminology and the history of the art, what you say is signified by the term highest vacuum and absolute vacuum in that deposition?"

Q. 469. That deposition being Mr. Waterman's deposition?

A. Yes. My answer was:

> "He defines that as a vacuum in the Coolidge tubes. He says that is the closest approach to an absolute vacuum that he can get."

I must have missed what the reporter got, namely, the fact that the question called for a reference to two terms, highest vacuum and absolute vacuum. What I answered was with respect to the absolute vacuum, which your Honor may recall Mr. Waterman related to the Coolidge tube. I think it is perfectly clear from Mr. Waterman's testimony that he uses the term highest vacuum over and over again with respect to the Fleming tube, and also that he means there the highest vacuum attainable by the lamp exhaust, which was what was used on the Fleming tubes.

Mr. Davis: Direct examination closed.

Mr. Edmonds: May I ask one more direct question so as to correct a minor matter in the record of yesterday?

The Court: Yes.

By **Mr. Edmonds**:

Q. 470. In your answer to Q. 42, you were referred to the General Electric tube UV-201-A. There is an exhibit in this case of the General Electric tube marked UX-201-A. Will you explain what difference, if any, there may be between those two tubes?

A. They are the same tube except for the base.

Q. 471. That is to say, contact pins on the under side of the tube?

A. Yes, otherwise they are the same.

Mr. Edmonds: That is all.

Mr. Haight: If your Honor please, I understand that part of Mr. Hogan's cross-examination is to be conducted by Mr. Darby who is away today and will be back here tomorrow morning and it was arranged between him and Mr. Davis, if agreeable to your Honor, that he should conduct his part of the cross-examination tomorrow morning.

Mr. Richmond tells me that he will conduct his part of the examination with a little more speed and dispatch if he can have from now until after recess to collect his thoughts and get them in some ordered fashion and possibly we can use up some of the time in offering other exhibits.

The Court: As you like. If you can save time by consuming the next half hour, all right, but we do not want to make it up and not gain anything by it.

Mr. Haight: I thought maybe it would be agreeable to your Honor to adjourn a little bit earlier.

Mr. Davis: This is the last witness. We have only left the matter of the notebooks about which I have talked with Judge Haight this morning.

The Court: And you are not ready with that?

Mr. Davis: I have not had an opportunity to talk to Judge Haight about it and there are a few exhibits to offer, and otherwise we are through.

Mr. Haight: There will be no difficulty about the notebooks. What Mr. Davis wanted is a stipulation that a certain notebook contained reference to certain matter only at certain pages. That will require an examination of the book by Dr. Arnold or Dr. Kelly and they will do it just as quickly as they can get to it. However, I want to have a little more clearly defined than Mr. Davis outlined it to me this morning exactly what he wants and I will take that up with him at recess.

The Court: Then we can save time by leaving counsel free until 2.15?

Mr. Haight: We can go ahead with some offers now and take some time up that way.

Mr. Davis: Mr. Howson has a few offers to put in evidence.

Mr. Haight: We will save time that way.

Mr. Howson: I offer in evidence the paper which was marked Plaintiff's Exhibit C for identification, being Compton & Van Voorhis paper and referred to during the examination of the witness Kelly.

(Received in evidence and marked "Plaintiff's Exhibit No. 194." *See Volume IV, Plaintiff's Exhibits, page 185.*)

Mr. Howson: I also offer in evidence from the Interference file of the Arnold-Langmuir Interference, paper No. 4, being Arnold's first preliminary statement.

(Received in evidence and marked "Plaintiff's Exhibit No. 195." *See Volume IV, Plaintiff's Exhibits, page 203.*)

Mr. Howson: I also offer in evidence from the same Interference file, paper marked No. 6, being Patent Office letter dated September 8, 1916.

(Received in evidence and marked "Plaintiff's Exhibit No. 196." *See Volume IV, Plaintiff's Exhibits, page 204.*)

Mr. Howson: I also offer in evidence from that same Interference file, paper No. 9, being Patent Office letter dated September 18, 1916.

(Received in evidence and marked "Plaintiff's Exhibit No. 197." *See Volume IV, Plaintiff's Exhibits, page 205.*)

Mr. Howson: I also offer in evidence from that same Interference file, paper No. 10, being Arnold amended preliminary statement.

(Received in evidence and marked "Plaintiff's Exhibit No. 198." *See Volume IV, Plaintiff's Exhibits, page 206.*)

Mr. Howson: I also offer in evidence from that same Interference file, paper No. 32, being Supplementary Motion of Arnold.

(Received in evidence and marked "Plaintiff's Exhibit No. 199." *See Volume IV, Plaintiff's Exhibits, page 207.*)

Mr. Howson: I also offer in evidence from that same Interference file, paper No. 85, being letter from the Secretary of the Navy to the Commissioner of Patents, dated February 7, 1918.

(Received in evidence and marked "Plaintiff's Exhibit No. 200." *See Volume IV, Plaintiff's Exhibits, page 208.*)

Mr. Howson: I also offer in evidence the Option of December 16, 1912, and Agreement of December 15, 1912, between Peter Cooper Hewitt and the American Telephone & Telegraph Company reproduced from page 1439 of the printed record in Hewitt against the A. T. & T. Co., referred to in the cross-examination of the witness Jewett.

(Received in evidence and marked "Plaintiff's Exhibits Nos. 201 and 201-A." *See Volume IV, Plaintiff's Exhibits, pages 210 and 214.*)

Mr. Howson: I offer in evidence copies of the Hewitt patents referred to in that agreement, the first being No. 781,001; 781,002; 749,791; 749,792; 749,793; 758,650; 954,434; and 991,304.

Mr. Haight: I would like to reserve the right to object to these patents. I do not know anything about them and I will have to confer with Mr. Richmond and Mr. Ballard about that.

The Court: You may do so if you desire to do so.

Mr. Howson: They are the patents enumerated in this agreement which has already gone into evidence.

Mr. Haight: But that agreement provided for patents that covered applications and patents that were to issue and things of that kind.

Mr. Howson: These are specifically enumerated by number in the agreement.

The Court: You may reserve a motion to strike. It will be given a number now.

(Received in evidence and marked respectively "Plaintiff's Exhibits Nos. 202, 203, 204, 205, 206, 207, 208 and 209." *See Volume IV, Plaintiff's Exhibits, pages 235-255.*)

Mr. Howson: I offer in evidence page 281 from the printed record in the Cooper Hewitt against the A. T. & T., table of repeaters referred to in the testimony of Mr. Gherardi.

Mr. Haight: I object to that. We have produced Mr. Blackwell here and testified exactly what the condition with respect to repeaters are.

Mr. Howson: The schedule I am offering was referred to by the witness——

Mr. Haight: Only on cross-examination.

Mr. Howson: And his evidence is more or less unintelligible without these papers.

The Court: What witness was that?

Mr. Haight: On the cross-examination of Mr. Colpitts, Mr. Colpitts, as your Honor will recall, testified that in—he said taking a day, for instance, January 1, 1915, I think it was, may be 1914, there was probably half a dozen repeaters in service; whereupon on cross-examination they showed him these tables which were contained in the testimony of Mr. Gherardi given in the Peter Cooper Hewitt suit against the Telephone Company.

The Court: That is what these are?

Mr. Haight: Yes, that is what these are, and they asked him various questions about it, Mr. Colpitts went back home and investigated the matter and then came down here and said he had made a mistake as to there being a half a dozen, and as a matter of fact there were thirty. Then we put Mr. Blackwell on to show exactly the repeater situation, mechanical and whatnot. The objection that I have to these exhibits, I mean the real objection to them, is that they refer to one-way repeaters and things of that kind, none of which has been explained, and I can not assume that the other side are going to attempt to offer in evidence pages of testimony given in another case, and consequently I have not attempted to go into that and explain this situation.

THE COURT: This page is not in the Interference record?

MR. HAIGHT: No. I think the whole repeater situation is covered by Mr. Blackwell's testimony.

MR. HOWSON: I do not think it is and I do not see that this cross-examination of Mr. Colpitts is intelligible without these things before the Court.

MR. DAVIS: My recollection is that Mr. Colpitts accepted this statement of Mr. Gherardi as being correct.

MR. HAIGHT: He said he supposed it was.

MR. DAVIS: I do not think it is at all important how many repeaters there were in the case.

THE COURT: What is the purpose of this? It is not for the purpose of contradiction?

MR. HOWSON: Not at all. It is to confirm what the witness said.

THE COURT: What he said is not disputed.

MR. DAVIS: It is simply a matter of understanding the testimony.

THE COURT: It was used and it was referred to and it was used as a basis of cross-examination and I think that it should be admitted as supplementing and explaining the cross-examination. If it should become necessary to call another witness, it is unavoidable, but it is so interwoven with the testimony, and it is not intended as contradictory testimony.

(Received in evidence and marked "Plaintiff's Exhibit No. 210." *See Volume IV, Plaintiff's Exhibits, page 261.*)

Mr. Howson: Similarly I offer page 290, which was treated in the same way at the same time.

The Court: That is as to repeaters?

Mr. Howson: Yes.

(Received in evidence and marked "Plaintiff's Exhibit No. 210-A." *See Volume IV, Plaintiff's Exhibits, page 262.*)

Mr. Howson: I also offer in evidence the Pring & Parker article in the *Philosophical Magazine*, Volume 23, 1913, page 212.

(Received in evidence and marked "Plaintiff's Exhibit No. 211." *See Volume IV, Plaintiff's Exhibits, page 263.*)

Mr. Howson: I also offer in evidence copy of the Fleming U. S. Patent No. 954,619, April 12, 1910.

(Received in evidence and marked "Plaintiff's Exhibit No. 212." *See Volume IV, Plaintiff's Exhibits, page 269.*)

Mr. Howson: I also offer in evidence copy of the DeForest patent No. 879,532.

(Received in evidence and marked "Plaintiff's Exhibit No. 213." *See Volume IV, Plaintiff's Exhibits, page 273.*)

Mr. Howson: I also offer in evidence, copy of the DeForest patent, No. 1,201,273, granted October 17, 1916.

Mr. Haight: What is the relevancy of that?

The Court: What is the relevancy of that?

Mr. Howson: I offer that in evidence because of the statements in this specification on page 2, line 39, showing that at that time DeForest tubes were ionizing tubes.

Mr. Haight: I do not think that that is admissible.

THE COURT: I do not see that, Mr. Howson.

MR. HOWSON: The evidence that has been endeavored to be put forward in behalf of DeForest was that earlier than this DeForest was saying that he was making these tubes——

THE COURT: The California depositions?

MR. HOWSON: Yes, and the arguments which they seek to draw from that; and here is evidence that the same man applying for a patent in this country after that is treating his tubes as ionizing.

MR. HAIGHT: I will ask that the offer of these two patents be withheld until Mr. Darby can go over that, because I am not familiar with the California testimony.

AFTER RECESS.

CROSS-EXAMINATION.

By MR. RICHMOND:

XQ. 472. The intensity of visible blue glow is proportional to the ionization, is it not, in any given tube?

A. It is proportional to the energy of the ionization current. I think that is what you can define it as, yes.

XQ. 473. And if the ionization increased the blue glow becomes more manifest, more intense, does it not?

A. As a general rule, yes.

XQ. 474. And reciprocally if the ionization decreases the blue glow becomes fainter?

A. Yes.

XQ. 475. And the reason why blue glow ceases to become visible is rather a physiological reason, the eye is not any longer able to appreciate the small quantity of energy coming to it as the ionization becomes less and less?

A. That certainly would be one reason. Another might be a radiation which you would not call blue, that is to say, there might be substantial ionization without a visible radiation by reason of the spectrum effect rather than the intensity effect.

XQ. 476. Would the spectrum change in any other way than in intensity as the ionization got less and less?

A. I do not know.

XQ. 477. You do not have any reason to suppose it would?

A. I was thinking of the change in color with reduction of pressure in an incandescent lamp exhaust where you get a pink glow at rather high pressure and a bluish glow at higher pressures. That might indicate such a change as I mentioned.

XQ. 478. And in cases of ionization where there is no visible blue glow there is radiation of energy from the residual gas, is there not?

A. I suppose there is some very small radiation of some sort.

XQ. 479. That radiation is probably proportional to the ionization, is it not?

A. It may be, of whatever kind it is.

XQ. 480. If I understood you correctly, you said that it would be impossible in a DeForest audion to heat the plate sufficiently by bombardment to get the gas out of it properly. Did I understand you right?

A. I think I used as an illustration there the power of five watts which would be enough to heat a plate to redness, about 800 degrees or rather dull redness, and said that at 100 volts the current would be 50 milliamperes, which unless my arithmetic was wrong would be far above anything you would expect to get from an audion filament. If the audion were pumped to a much higher vacuum so that a higher voltage could be used for electron bombardment it is conceivable that the energy required to heat the plate could be had at a smaller current which the filament would support.

XQ. 481. So that if it were pumped adequately or properly you think it might be that you could heat the plate sufficiently by electron bombardment?

A. I think that it is perfectly clear that what you need to heat the plate is power, energy delivered on the plate and that if you are limited in current and if other conditions are right (whatever those might be) you could with a lower current get a heating effect by increasing the voltage and therefore the impact by the electrons corresponding to that lower current. Whether that could be attained or not in pumping in any except a carefully treated tube I do not know. I do not think it could.

XQ. 482. And in raising the voltage you could go away over on the saturation part of the characteristic, could you not, for bombarding the plate in connection with pumping?

A. If there were no gases present you could increase the voltage and of course be limited by saturation current. That is about what I said, yes.

XQ. 483. Do you mean that you have to get practically all the gas out in order to remove the gas by bombardment?

A. I mean that you would have to have the tube so well treated that if the initial bombardment were accompanied by a glow, because of the high voltage used, that glow would not increase the pressure or put gas back into an electrode or into the walls of the tube so that it would come out later. I think it is a question of the pre-treatment of the tube.

XQ. 484. I thought it was the pre-treatment that we were talking about. I thought you assumed that the DeForest audion had not been pre-treated?

A. That is correct.

XQ. 485. And I want to know about the treatment to which it must be subjected to make it a high vacuum tube. Is it not true that if you have a good pump and keep pumping you can gradually increase your voltage and get up to a sufficient dissipation of energy to clean up the plate, of course, assuming that the tube is being baked meanwhile in the usual manner?

A. And I suppose assuming that the grid is tied in to get the benefit of the bombardment, and that your pump is adequate to remove all the gas that comes out. I suppose one could even with a limited filament emission of a few milliamperes get a reasonable clean-up in that way. I think we would have to make other tests to find out just what could be done under specific set of conditions.

XQ. 486. Referring to audion 20.2 and the characteristic curves shown in Arnold Priority Exhibit 19, sheet E. S. 86,907, I understood you to say that those two loops drawn in solid lines were in your opinion due to gas, is that right?

A. I think I said that loops of that sort in the saturation range were usually gas effects on the filament in changing its surface conditions, and I thought that that was a fair explanation of those changes reflected here.

XQ. 487. You are not willing quite unqualifiedly to commit yourself on your judgment of these loops?

A. I think that is the best that can be made of that. I think it is not a temperature effect.

XQ. 488. Why do you think that those loops are due to gas, those particular loops in that blueprint?

A. Because the changes in emission are large and irregular and change with time so that they would be the sort of thing to be expected from a change due to some chemical action of gas on the surface or due to a change, a physical change due to bombardment by gas ions.

XQ. 489. And in what respect are they different from what you would get if there was a gradual decline in the temperature of the filament as time goes on?

A. A gradual decline of temperature as time goes on would cause a gradual decrease in emission, and these are gradual increases with respect to the first part and with respect to the return loops, so to speak, they are the sort of thing which is too irregular to be accounted for, I think, by a simple change in temperature occasioned by running down of the battery for instance, or something of that sort.

XQ. 490. In your last answer I understood you to say that there was an increase of one part and a decrease on the other. Are you sure of that?

A. I mean that the curves go to a very high point before they start to break down.

XQ. 491. When this curve is going up initially and begins to form the upper loop, saturation is not attained until it gets to the upper part of the loop, is it?

A. That may be. I do not know just where it is coming in. I do not know where it begins.

XQ. 492. I understand that saturation means when you are getting all of the electrons that are emitted and if there is no change on the filament you are not getting them until you get up to the top of the loop?

A. There is no flat part indicating saturation until you get to the top.

XQ. 493. And when you get to saturation you have with time a decreasing emission until you get back onto the space charge part of the curve?

A. You have a decreasing emission, certainly a decreasing space current. I do not know that that vertical portion is the space charge part of the curve, at least until the curve is returned to the same point.

XQ. 494. Suppose we assume, as you suggest, that these loops are due to gas. Would it require enough gas to make those loops to materially affect the space charge part of the characteristics?

A. I do not know, Mr. Richmond. That is what I said this morning.

XQ. 495. In the middle of this same sheet E. S. 86,907, is a dotted characteristic curve for audion B-19. You testified about that this morning, did you not?

A. We referred to that, yes.

XQ. 496. And that is the characteristic on which the Board of Examiners in Chief named a date for reduction to practice for Dr. Arnold, is it not?

A. I do not know.

XQ. 497. Did I understand you to suggest this morning that irregularity in behavior of the audions used at the repeaters in Philadelphia in the latter part of 1913, would be a cause for faulty balancing?

A. I think I pointed out that it was difficult to balance anything that changes and that consequently with reference to that Philadelphia work changes in the audion constants in operation would make it difficult to balance.

XQ. 498. Will you point that out a little more specifically, just how would the difficulty come in and if you care to I will suggest referring to Defendant's Exhibit 59, which is a diagram for a telephone repeater, in connection with your answer?

A. The point is simply that in order to balance any opposing amplifying circuit, one must keep the amount of reflected power, if I may call it that, down below a point where it will produce the singing effect, that is to say, if there is too much energy reaching the input circuit of either tube from its output side, that will force the whole system to break into some particular oscillation usually of audio-frequency and produce the harmful effect that we call singing.

If the repeating element is not uniform but at one instant puts out more power than at another instant, or if its characteristics change so that the balancing network, as I understand it, is not a true replica or a reasonably true replica within these energy limits of the lines it is intended to balance, and if the constants of either of those circuits are affected by changes in the repeating element, then the balance cannot be maintained and one has to do either or both of two things, cut down the amount of amplification, that is to say, the gain, or steady the conditions so that things remain fixed and the transient irregular effects do not occur.

No matter how much one may reduce the amplification alone so long as he was getting a real amplification he would not be able to stop singing, if the irregularities persisted, but if the two things come down together then the singing can be stopped.

XQ. 499. There were just a few words in your last answer which seemed to indicate that, aside from changing the degree of amplification, a change in the audion might change the condition of balance between the line and its network. You did not mean that, did you?

A. Any change of impedance in any circuit connected to any other circuit through transformers or directly will change the effective constants of the connected circuit and if such changes produce different effects on the line side and on the balance side then of course they would not remain compensated. If they produce the same change then they would be compensated.

The point is, putting it very roughly, you can not get a balance for changing conditions, but without changing conditions you can get a balance even with higher gains, using apparatus that is balanced to the same degree of precision.

XQ. 500. Your position is that if the amplification given by the audion is variable then although you may at one time have it down low enough to avoid singing, this variability may at some other time bring it up high enough to produce singing; is that what you mean?

A. I think that is not the whole point. I do not think that the only change that would make trouble would be one of amplification. I think that general changes of voltage-current relations, of impedance, would be reflected unequally to systems connected to a plate circuit and to a grid circuit on a tube, so that a shift in constants other than mere amplification would be likely to destroy balance.

XQ. 501. Do I understand that it is your judgment that the singing at Philadelphia was due to such irregularities in the audion elements there?

A. I do not know enough about the Philadelphia circuit to state that as a fact, but I consider that a very probable occurrence. I think that the audions not merely were reduced in amplifying power by cutting down plate potential but also increased in steadiness.

XQ. 502. In reaching that opinion, have you given consideration to the matter of the spacing of the loading coils on the lines that were balanced by the net works?

A. No, not specifically.

XQ. 503. Did you give consideration to the design of the balancing net works?

A. Not specifically, I do not think we had any real data as to that.

XQ. 504. Did you give consideration to the arrangements that were incorporated in the system for ringing currents?

A. No, except that I knew that they were there and should not have affected the points I mentioned.

XQ. 505. Do you mean that the arrangement for ringing did not produce any unbalance?

A. No, I do not mean that. They would have to be compensated for.

XQ. 506. And is that an easy thing to do?

A. Probably not. No balancing operation is easy.

XQ. 507. Did you take into consideration the arrangement for superposed telegraphy on the line; what they call compositing?

A. No, I did not even know that those lines were composited.

Mr. Davis: I move to strike out the question because there is nothing in the testimony about this imposition of telegraph lines. I think the question here should be confined to the data given to the witness and given to the plaintiff.

The Court: I will hear you, Mr. Richmond.

Mr. Richmond: It is my impression that those features show on the blueprints. That is what I was relying on.

The Court: You are not trying to introduce new factors into the situation?

Mr. Richmond: No.

The Court: Then Mr. Davis challenges that and can you show that there is evidence in the case to support your contention?

Mr. Richmond: The circuit diagram is too complicated for me and I will cheerfully withdraw the question.

By Mr. Richmond:

XQ. 508. It is an important factor in the matter of balancing lines with net works whether the impedance characteristic of the transformer is non-linear with respect to frequencies, is it not?

A. I think that would certainly have to be taken into consideration; if you are balancing for all frequencies you must include any distortions due to transformer efficiency changes as well as line changes generally. I am making that statement not from great experience with telephone line balancing but from the analogous balancing of radio receivers.

XQ. 509. And it is a fact that it has been a very difficult problem to get transformers with linear characteristics over a range of frequencies, is it not?

A. I know that it takes skillful design to make a transformer that will give reasonably uniform efficiency over a very wide range of frequencies, that is, within the audio range.

XQ. 510. I understood you to say that the characteristic curve for Western Electric tube 102-D in Plaintiff's Exhibit 187 would approach the 3/2 law if the voltage had been carried high enough. Did I understand you correctly?

A. My point there was that this tube was behaving in spite of its high amplification constant, and the consequent exaggerated effects of the contact potential and filament drop, it was behaving as good tubes in my experience ordinarily do behave.

The curve was showing a decrease in slope tending toward a 1.5 slope at the higher voltages where the masking effects of which I have spoken are less prominent in proportion to the actual voltage used. That is shown by this plot and I think I hazarded the view that if I had had higher voltages this would probably have continued further with that bending and therefore approached still more closely, but I also stated that I did not have those voltages and therefore I could not offer the view as a fact.

XQ. 511. In any case where you have a tube with a steep characteristic, that is steeper than 3/2, it is going to bend over and pass through the 3/2 value as it approaches saturation, is it not?

A. Yes, I mentioned that also. That is to say it was hard to tell whether we were approaching saturation in some of these other curves and without data based upon changes of filament temperature it would be difficult to resolve that. I think we all recognize that even with a good tube, if for some reason the steep slope exists, as that gets into saturation, the transition effect will pull the slope down.

XQ. 512. Now, in Plaintiff's Exhibit 186, which is your characteristic for audion 64, you did not draw a 3/2 slope line through the top point as you did for the Western Electric 102-D tube on Plaintiff's Exhibit 187, did you?

A. There is no line drawn here, no. There is a slight decrease in slope at the value 125, 131 microamperes which may again represent a transition approach, that is, an approach toward saturation. Of course, the point I was discussing in connection with that curve was the increase in slope in the neighborhood of 25 and 30 volts, which I think does not appear in the 102.

XQ. 513. It seems to me that that is another matter. Though perhaps that would constitute an excuse for not drawing the line in one case although you did in the other?

Mr. Davis: Is that a question?

Mr. Richmond: Mr. Davis, I seemed to be questioned and I was trying to answer. I will get away from it as quickly as I can.

XQ. 514. The remarks that you just gave about the factors that reduce the slope of a curve at higher voltages would be exactly as applicable for Exhibit 186 for audion 64 as for Exhibit 187 for the 102-D tube?

A. The effect of transition toward saturation would be but with an increasing slope around ionization potentials I think the disappearance of the other complicating factors would be much less important, if important at all.

XQ. 515. I understood you to remark in connection with Defendant's Exhibit 54, which is a plot of the data by Dr. Kelly for tube 9.111 that with positive voltages on the grid, the grid currents should have been included?

A. I think I said they should have either been included or shown to be negligible, and that the fact that the zero grid curve after correction was not parallel to the other three indicated that one had best not put much reliance on the other three in the absence of that information.

XQ. 516. Is that your only ground for thinking they were not negligible?

A. I do not know anything about the tube except that four volts and even 2.6 volts and probably 1.5 volts on the grid may give currents which would have a substantial effect.

XQ. 517. If these positive grid currents were to be taken account of it would be in some such equation as that discussed by Dr. Langmuir and indicated at the right of Defendant's Exhibit 54?

A. It would be in some such equation only when one is considering the effects of the combined potentials.

XQ. 518. Now, please look at the bottom of page 278 of Plaintiff's Exhibit 104, which was Langmuir Exhibit 84, in the Interference, Langmuir's Radio Engineers paper, read April 7, 1915, and published September, 1915, in the official publication of the Institute of Radio Engineers, and see if I am correct that the equation there is given for the current to the anode alone?

A. The quotation with reference to this or the passage with reference to this equation is "For different anode potentials, these curves are shifted vertically, by amounts proportional to the change in anode potential. In fact, it is found that these curves can be represented with fair approximation by a function of the form"—and then follows the equation—"Where i is the current flowing to the anode V_a is the voltage on the anode, V is the voltage on the anode, V_g the voltage on the grid, and k the constant which depends on the relative shapes and positions of the electrodes." I think therefore that "I" is intended to be the current flowing to the anode for that approximation.

XQ. 519. Referring to Plaintiff's Exhibit 188, produced by you this morning, this relates to the peanut tube, an exhibit produced by Van der Bijl?

A. I do not know what tube it related to except that it was characterized by Van der Bijl as a small receiving tube.

Mr. Richmond: I presume there will be no need to get the witness to verify it. That is correct. The record shows that this was a tube developed for aeroplane use during the war.

By Mr. Richmond:

XQ. 520. On this diagram of yours, Exhibit 188, where did you get the 12½ volts that you applied as a correction?

A. That was a value chosen by making a 2/3 plot and getting the intercept, as I recall, that is to say, it was noted when the lower voltage, I think 8, used by Van der Bijl, was applied, the curve was not a straight line on the 2/3 plot or a current plot generally, and therefore, a higher value was determined by the intercept method.

XQ. 521. The value of 12.5 is determined by discovering what value is necessary to come closest to the 3/2 law, is it not?

A. I do not think it is fair to state it that way. The value is a value that could be determined with information had by the measurement of contact potentials and the amplification constant, and it can also be determined by drawing the curve for which we have a reasonable theoretical basis, namely, the 2/3 power curve and taking the intercept from that. You might call that finding the value which fits the 3/2 power but I think that contains an unfair implication.

XQ. 522. Is not that exactly what your second method amounts to? You mentioned two ways, one is to find out by some direct method of measurement what the contact potential is or to find this intercept, and if you use the second method you are really finding the value that will bring the curve nearest to the 3/2 power law fit?

A. That is the result, yes. But there is a very good physical basis for it.

XQ. 523. On that diagram that you have before you for the peanut tube, Plaintiff's Exhibit 188, I notice the legend "Corrected for contact potential difference." Do you not think it would have been more accurate to have said corrected for assumed contact potential difference?

A. I have no objection to that. The assumption is the same type as that used by Van der Bijl in connection with the other constant.

XQ. 524. Referring to Exhibit 189 introduced by you this morning I ask your pardon if I am asking for a repetition, but will you please tell me how those curves were obtained?

A. These particular curves were taken from the current voltage data given by Van der Bijl in the record and were plotted from that. The amplification constants were determined for the changes in anode volts for change of grid volts and the intercepts determined the corrections of anode voltage for the plot on 189-A.

XQ. 525. And what did you find for that intercept?

A. The two corrections are minus 55 for grid volts zero and minus 475 for grid volts minus 35, that high value of course representing not only a contact potential but a filament drop to be included in connection with the amplification constant of the tube.

XQ. 526. And these values were ascertained from 189-A and then were embodied in 189; is that correct?

A. No, I think the process was the other side up. Dr. Dushman made the computations for me and I think that was his process.

XQ. 527. 189 shows how the intercept values were obtained?

A. I think that is correct.

XQ. 528. And on 189-A the resulting plots are given by making those corrections?

A. I think that is the method used.

XQ. 529. Did you do this in all your plots that you introduced this morning?

A. I should have to see all these plots to say.

XQ. 530. Here they are.

A. Exhibit 188 is taken directly from Dr. Kelly's data. Exhibit 187 is similarly taken directly from that data. Exhibit 190 is taken from actual measurements of a UX-201-A tube and shows the effect with the commutator and of the application of minus one volt. Exhibit 193 is taken directly from Dr. Kelly's data. Exhibit 191 is taken directly from Dr. Kelly's data. The corrected curve on Exhibit 192 is taken directly from his data. It would appear that the only two in which we did not know the relations of which we were speaking were those two that you and I have just discussed.

XQ. 531. I understand that in these other cases you consider that there was no occasion for such a correction as you made in Exhibit 189 and 189-A; is that right?

A. It depends on what one intends to do with the data, what one is looking for. I think that I was showing in one case the effects of those uncorrected masking properties.

XQ. 532. Which case was that?

A. In 186 there was no relation to this situation at all. There I was showing the upper change in slope carried by the observed numbers. In 187 I showed how the factors as plotted gave a curve which was approaching, with this high amplification tube, this 3/2 slope as the voltage increased. Conceivably that could be corrected for in the same way if one determined what the effects of the potential drop on the filament and contact potential as influenced by the high voltage amplification of the tube, and in that way compensate for that departure or that steepness in the lower part of the curve, but that was not done.

Similarly on Exhibit 190, I was trying to show what the effects of measurement with and without a rotating commutator and with and without a corrected potential amounted to. With reference to 193 there again we have a tube which, as the data is provided, shows a steeper slope approaching a 3/2 power slope and I have no doubt that the effects which make that slope steeper could be compensated for by measurement, but it was not done as you suggest. On 191 I think the same is true. As to 54-A, that factor did not come in at all.

XQ. 533. The data for Plaintiff's Exhibit 190 produced by you were obtained from a different tube than the identical tube of the Warner paper?

A. Oh, yes, I did not know what tube Warner had and these tubes vary a little from one tube to the next, but they are rather close to the figures that Warner used. It was a typical 201-A tube in any event.

XQ. 534. What was the basis for assuming that value of minus one volt, that you have for curve C, on Exhibit 190?

A. I believe that value has been measured time and time again and the normal value for this type of tube was used.

XQ. 535. You mean that that is an ascertained and stated voltage value pertaining to that type of tube?

A. I do not know that that voltage would apply to all 201-A tubes. In fact, I think there are variations as the manufacturing process are changed in detail; but I have no doubt that that value was determined for that particular tube.

XQ. 536. Was it determined so as to bring the curve as near as possible to the 3/2 power law?

A. I think not. I think that was the result, but I do not think that was the purpose.

XQ. 537. And you do not think that that was the method by which the value was arrived at?

A. No.

XQ. 538. Do you know?

A. No.

XQ. 539. Please tell us just how you got this minus one volt, was it on somebody else's authority?

A. Yes. I took that from the General Electric records. Dr. Dushman plotted the curves for me.

XQ. 540. In this curve C on Exhibit 190 you have made no correction for the initial velocities of the electrons, have you?

A. I think that would be included in the correction, both that and filament drop effect, because the filament drop effect is compensated for by the commutator. There is no specific correction for it unless it is included in the additional voltage supplied to the grid.

XQ. 541. Is it included?

A. I do not know.

XQ. 542. If it is not included then if you made that correction it would take your points off from the 3/2 law materially; would it not?

A. I think the change would be very small.

XQ. 543. I understood you to say that the 3/2 power law which was propounded by Dr. Langmuir is often used as a test of a working tube. Do you know of any purchase specifications for practical tubes that recite this law?

A. No, I do not know anything about purchase specifications.

XQ. 544. Do you know of any manufacturing specifications for vacuum tubes?

A. No, I am not familiar with them, so that I do not know whether they are in or out.

XQ. 545. Do you know of any catalogue information which refers to this law?

A. No, I have never seen any.

XQ. 546. In all of the curves by Dr. Kelly that you considered this morning the data were plotted directly without any corrections at all, were they?

A. I assumed so with the exception of 54 in which there was an error in plotting. I have not checked them, but I assume that Dr. Kelly would plot them correctly.

XQ. 547. But by corrections I mean adjustments for what are supposed to be disturbing factors?

A. I think he plotted his data as he observed it, if that is what you mean.

XQ. 548. Yes. He plotted his volts and amperes as they were obtained——

A. Of course, I do not know. All I can say is that he has given us certain voltage current data and that those are the data reflected by the plots. Beyond that I do not see how I can go. I do not know what adjustments he made before he took the experimental data.

XQ. 549. Have you had any practical experience in telephone engineering?

A. I have never worked for the Telephone Company, if that is what you mean. I have had a great deal of practical experience in audio-amplifying work connected with radio, that is, with the use of audio transmission over wires in so far as they are involved in reproduction of speech and music and amplification of the voice or telephone currents to radio transmitters or what-not, but I have never worked in the telephone plant either as an engineer or investigator.

XQ. 550. Restricting yourself to wire telephony just give us a little more idea of when and where you have had such experience?

A. I have had no experience at all on the telephone company's lines. I have for years been familiar with the transmission of telephone currents over wires in connection with radio apparatus. While that is not wire telephony, but merely an extension of the radio apparatus it involves the same phenomena and is the same thing from the purely physical point of view. I am not sure just what your question is directed to, but I do not want to pose as a practical telephone engineer who has had any experience at all in connection with the Telephone Company's line work.

XQ. 551. And that experience you speak of, does that include two-way telephony?

A. I have had a little experience with two-way telephony, but not a great deal.

XQ. 552. What do you mean by a little?

A. That is to say I have balanced one particular audio-frequency against another particular audio-frequency, but I have never experimented on a commercial or even experimental or artificial voice line with the telephone company's repeaters.

XQ. 553. What practical experience have you had in the matter of balancing telephone lines for repeater work?

A. None on the telephone lines. I have had the physical equivalent of that in connection with audio-frequency work, but as to the manipulation of the telephone company's plant I pretend to know nothing other than the things which would be based upon definite physical consideration that I know as a matter of engineering.

XQ. 554. When you testified this morning about balancing, on what did you base your knowledge of that matter?

A. Certainly not on a detailed knowledge of the telephone company's plant, but on an engineering knowledge of the physical fundamentals involved in such work.

XQ. 555. How long a line did you have to balance in this audio-frequency balancing that you have just mentioned?

A. Nothing but laboratory work, not a balancing of an outside line at all.

XQ. 556. Just balancing one artificial line against another?

A. Yes, I would not even call them artificial lines because they had lumped constants rather than distributed constants.

Mr. Richmond: That is all of my cross-examination. I understand Mr. Darby has some further plans for cross-examination.

Mr. Davis: There is no redirect on this cross and we reserve the witness for Mr. Darby's further cross-examination.

It seems to us proper to show the relation of the Telephone Company to this patent. It is already stated in a general way in a letter which Mr. Folk wrote to the Law Examiner in the Interference which is now in.

I offer in evidence this contract or copy of a contract entitled "Modification of License agreement dated July 1, 1920, between the General Electric Company and the American Telephone & Telegraph Company," to which I understand there is no objection.

(Received in evidence and marked "Plaintiff's Exhibit No. 214." *See Volume IV, Plaintiff's Exhibits, page 277.*)

Mr. Davis: I understand it is stipulated that H. D. Arnold and the Western Electric Company began an equity suit on April 29, 1926, against

Irving Langmuir and the General Electric Company in the United States District Court for the Southern District of New York under Section 4915 of the Revised Statute, praying the Court to adjudge Arnold the first inventor of the subject of the claims which were in interference 40,380, and praying the Court to authorize the Commissioner of Patents to issue to the Western Electric Company, Inc., as assignee of Arnold a patent for the subject matter of the interference, and that such suit is now pending undecided in the Southern District of New York.

Mr. Haight: It has never been tried.

Mr. Davis: I understand the Bill was filed and the answer is filed and the case is in that condition.

Mr. Haight: That will be stipulated, but I do not see the materiality of it, but if it has any materiality it can be made to appear by the stipulation—I do not mean the materiality may be made to appear, but the fact which is stipulated, I do not think is material.

The Court: You agree to stipulate anyway and give them an opportunity to show the relevancy and materiality at any time in the future.

Mr. Haight: Yes. I will not ask your Honor to pass upon it now.

John V. L. Hogan, resumes the stand.

Cross-Examination (Continued).

By Mr. Darby:

XQ. 557. Am I correct in understanding that you measured the pressure of the early Fleming valves?

A. Not of the Fleming valves.

XQ. 558. You have not measured the pressure of the early Fleming valves?

A. Not of the Fleming valves.

XQ. 559. I rather got the impression from your testimony on page 1660 of the record, from the discussion had at that time that you had and I wanted to clear it up.

A. Were not we talking about audions there?

XQ. 560. Yes, we were. And the next question, and perhaps my last, you have measured the pressure of the early DeForest audion?

A. I have measured the pressure of tubes which I bought from DeForest in 1914 and 1915.

XQ. 561. You have not measured the pressure in tubes of 1912?

A. No.

XQ. 562. And when did you measure the pressure of the 1914 and 1915 tubes?

A. Some time in 1925, I do not remember just when.

XQ. 563. In 1925?

A. Yes.

XQ. 564. What method did you use in measuring it?

A. The gas test, so-called, calibrated from a duplicate tube as Dr. Kelly described in connection with his measurements.

XQ. 565. And you have no way of telling whether or not the condition in the tube had changed from 1914 to 1925?

A. None, except that the performance was about the same.

Mr. Darby: That is all.

Mr. Davis: No re-direct.

(Witness excused.)

DEFENDANT'S SUR-REBUTTAL PROOFS.

JOSEPH A. BECKER.

Joseph A. Becker, was called as a witness in sur-rebuttal, on behalf of the defendants, being duly sworn testified as follows:

Direct Examination.

By Mr. Richmond:

Q. 1. Please state your name, age, residence and occupation.

A. Joseph A. Becker, twenty-nine years, residence is Denville, New Jersey, and occupation is Research Physicist for the Bell Telephone Laboratories.

Q. 2. Please tell us in outline about your experience and training with discharge phenomena in vacuum tubes?

A. As an undergraduate I specialized in physics and then after receiving my Bachelor's degree I was employed by the Bureau of Standards in research work and later on by the Westinghouse Electric & Manufacturing Company in East Pittsburgh, and also at what was then the research organization of the Western Electric Company in New York. After this I returned to college for my doctor's degree and during this time did research work involving discharge phenomena, especially X-ray tubes.

Upon receiving my degree I was awarded a National Research Council Fellowship in Physics and for two years worked in that capacity under the direction of Dr. Millikan in California.

During this time I was working on a problem involving discharge phenomena, especially in connection with soft X-rays, that is, lower voltages than are used in an ordinary X-ray tube. Soft X-rays are X-rays which do not penetrate very much through ordinary matter. During this time I had to familiarize myself with discharge phenomena.

Also in that laboratory there were some thirty-odd experiments going on, most of which dealt with discharge phenomena and I was actively interested in most of them, talked with the people that did the work and discussed their problems and also discussed any particularly interesting features of them; also once or twice a week we had meetings at which topics of especial interest occurring in the literature were discussed and most of those dealt with atomic physics, and a good many of them dealt with discharge phenomena. During this time I was able to gather information from the experience of very many renowned physicists who occasionally came to see us.

In 1924 I was employed by the Engineering Department of the Western Electric Company in the Research organization and later on the name of this organization was changed to the Bell Telephone Laboratories.

Since 1924, I have been engaged in vacuum tube work, especially in connection with thermionics, or the emission of electrons from hot bodies. I might say that before being employed by the Western Electric Company during this interval between the time that I was serving as a National Research Fellow and the time at which I went with the Western Electric Company, I was an assistant Professor in Physics at Stanford University and during this time I gave a lecture demonstration course on modern physics.

Q. 3. From what institution did you receive your doctor's degree?

A. From Cornell University.

Q. 4. To what extent are you familiar with Plaintiff's Exhibit 99 in this case which is Sweetser's notes of his experimental work in and about August, 1912?

A. I have carefully gone over these notes and I familiarized myself with the experiments which they performed and the procedure during these experiments and the methods of working up the results.

Q. 5. Referring to Plaintiff's Exhibit 163, which is based on a part of those notes, can you distinguish successive stages for the events that are there recorded?

A. Yes, I believe it is convenient to divide this experiment into three stages. During the first stage, as recorded in both run 1 and run 2, the current is limited by the temperature of the filament. The blue glow pervades the whole tube and the current is independent, to a great extent, of the voltage between the filaments, the separation of the filaments, the size of the bulb, and various other factors.

The temperature is about the only thing upon which the current depends in this first stage, that is, the stage while the pressure is changing from five microns to about .54 microns.

Then I think it is convenient to call the short time interval during which the current suddenly drops, the second stage.

Then the third stage is the one when the pressure is less than about .54 microns and during this stage the current does not depend on the temperature of the filament but does depend on quite a number of other things, the chief things being: the distance between the filaments, the voltage between the filaments and the gas pressure.

So that I should say it is convenient to divide this run or these runs into three stages as I have stated.

Q. 6. Referring to that sudden decrease of current to which you have apportioned the second stage, was this a new type of phenomenon in August, 1912?

A. I do not think so. This sudden disappearance of blue glow accompanied by the sudden drop in the current I think was well known and had been met with in lamp clean-up as was testified several times before. In the clean-up of these lamps the blue glow would suddenly disappear, also it was the same phenomenon as occurred when in the audion as the pressure decreased the blue glow disappeared. So that as far as the sudden disappearance of the blue glow goes and this disappearance is always concommitant with a decrease in the current, I should say that the phenomenon was not new.

Mr. Davis: I move to strike out the portion of the answer that has to do with the disappearance of blue glow in the audion as being an attempt to establish something about the audion that has never been suggested in this case at all, and therefore entirely improper sur-rebuttal. I have no objection to the testimony about the lamps, because that has been talked about, but bringing in entirely new testimony as to what goes on in an audion is improper when the DeForest audion was never pleaded, is entirely improper.

Mr. Richmond: Your Honor, it seems to me, if my memory does not fail me, that Colpitts and Arnold both told about how the blue glow suddenly blinked out in an audion. It is a tedious matter to hunt it up, but I have not thought of it as being challenged and if Mr. Davis insists I will consent to strike it out.

Mr. Davis: I do not want to begin the case all over again and therefore I do insist.

By Mr. Richmond:

Q. 7. What does this sudden decrease of current that you have referred to as the second stage, what does that signify?

A. It signifies that there was a new type of discharge. Before the drop the current was limited by the temperature of the filament. After the drop it was limited by space charge. That is all it signifies.

But when I say limited by space change I do not want it to be understood that this is equivalent to saying limited by a pure electron space charge. All that there is necessary for this drop to occur is that subsequent to the drop the current should be limited by space charge. That might be a mixed space charge and the current might still be greatly influenced by positive ions. The mere occurrence of the drop tells you nothing whatsoever about the purity of the discharge subsequent to the drop.

Q. 8. On what does the magnitude of drop of current depend?

A. The easiest way to answer that is to see clearly on what the current depends before the drop and on what it depends after the drop. Before the drop it depends on the temperature of the filament and practically on that only. After the drop it depends on the distance between the filaments, the voltage between the filaments and the pressure of the gas that is present. If we keep the distance between the filaments constant and the voltage between the filaments constant and vary the temperature only then we can make the drop big or small; and instead dropping from 16 to 5 milliamperes we can make it go from 100 to 5; or by decreasing the temperature lower than was used in run 1, we could make it change from 6 milliamperes to 5 or by placing the temperature a little bit lower still we can make it that there is no change at all practically during this period 2, whereas subsequent to this we would still get any changes due to changes in pressure.

So that the magnitude of the drop can be made anything you please within limits by changing the temperature of the filament and keeping the distance between the filaments and the voltage across the filament fixed.

This is well illustrated by run 2. In run 2 the temperature of the filament was a good deal lower than in run 1. In run 1 it was 2225 degrees and in run 2 it was 2105 degrees. In run 2 the drop is quite small. There is a slight complicating factor in this case due to the fact that for run 1 the voltage was 250 volts and for run 2 it was approximately 200, but even for the second run if the voltage had remained at 250 the magnitude of the drop would have been quite small compared to the magnitude of the drop in run 1.

Q. 9. Is the occurrence of this phenomenon, this sudden drop in current value, conditioned by structural features and if so please explain about them?

A. As I have already mentioned, the distance between the filaments enters into the magnitude of the drop; but there is a very important other factor, namely, the change in the wall charge. This sudden drop is dependent upon and conditioned by a sudden change in the wall potential. If you have a tube in which the anode encloses the cathode, such that there are no changes in the wall charges or if there are any they cannot reach into the place where the discharge is taking place, that is, between the cathode and the anode, if you have the anode completely enclosing the cathode it is then my belief that you would not get such a sudden drop at all and the more nearly you approach that condition, that is, the more nearly the anode completely encloses the cathode, the less prominent this sudden drop becomes, so that I should say in summing up my answer to your question that it is dependent upon and conditioned by changes in wall potential.

Q. 10. Can you trace the changes in the wall charge during the experiment that is recorded on that Exhibit 163 through those three stages that you have mentioned?

A. I think I can. Suppose we begin at the beginning of this experiment and let us take run 1 as an illustration. At the beginning of the experiment when the pressure is approximately 5 microns the wall potential is quite close to the potential of the anode; that is, if our cathode is at zero potential and our anode is at plus 250 volts, then at the beginning of the run the wall potential will be about plus 250, pretty nearly the same as the anode.

As the pressure decreases it is found that the potential on the wall moves towards the potential of the cathode, and for example, about the middle of the first stage, the wall potential might be plus 100 volts, that is, the cathode is at zero and the wall is at plus 100 and the anode is at plus 250.

Then when we approach the condition where the second stage is about to begin, that is where the blue glow is about to disappear, we then find that the wall potential is, let us say, about 15 volts positive with respect to the negative end of the filament. If, for example, we have a 10-volt filament drop, the wall potential might be somewhere in the neighborhood of plus 15 volts. Then when the drop occurs and immediately after the drop one finds that the wall potential has changed from plus 15 to something like 4 or 5. The exact amount depends on various other factors but is of that general order and I should say that under that condition the walls are still positive with respect to the negative end of the filament, not very greatly positive but still positive.

Then as you pump out more gas and as you go even beyond the pressures which were used in run 1 of Plaintiff's Exhibit 163, that is, as you actually pump the gas out of the tube and get a good vacuum, then and not until then do the walls assume a negative potential with respect to the negative end of the filament. These figures I have given are general.

If you modify the type of structure sufficient to bring out just certain points I would not dare say that it was impossible to have the wall negative immediately after the drop, but from my experience I should say that one would have to take a very special structure to do that. And in general the walls are positive, slightly positive immediately after the drop and they do not become negative until the pressure is decreased considerably. But the most important thing I think is that just before and just after the occurrence of the sudden drop the wall potentials undergo a sudden change.

Q. 11. In your opinion what is the significance of this sudden drop relative to the question of the purity of the electron discharge immediately after the drop?

A. I certainly think that it does not mean that immediately after the drop the discharge is a pure electron discharge; in fact quite the contrary is true. I think the mere fact that you get this sudden drop is an indication that immediately thereafter you are still removed from a pure electron discharge and that you have to reduce your pressures to quite an extent, something like a factor of 8 or 10 before you really at that voltage have a pure electron discharge in which the positive ions play a non-substantial part.

Q. 11a. Can you say anything about the value of the current soon after this sudden drop as compared to its ultimate value when the pressure is very low?

A. Yes, I can. Immediately after the drop the current has a certain value which depends on various factors. If you now decrease the pressure by a factor of 8 or 10 or it might be 5 in a particular type of structure, but if you decrease the pressure by a considerable amount, then you find while you are decreasing the pressure the current decreases continuously and it is not until you have reached a good deal lower pressure that the current then becomes independent of the pressure, that is, independent of a still further decrease of pressure; and when you have reached this stage the current is two to three times lower than the value of the current soon after the break. In some cases I think it is possible to get the current to reduce by a factor of five and in case you have an anode which partly encloses the cathode that factor can be made even greater.

Q. 12. Referring to what you have distinguished as the third stage of Plaintiff's Exhibit 163, what evidence is there in Sweetser's Notes, Plaintiff's Exhibit 99, as to further change of current with further change of pressure after the drop?

A. If we consider only points in Plaintiff's Exhibit 99 for which the current was not fluctuating rapidly, then every single time that the pressure was decreased the current decreased. I think this is illustrated very well in the plot of the logarithm of the current versus the logarithm of the voltage, part of which has been shown before.

On this sheet which is a logarithmic plot of the current in milliamperes against the voltage between the electrodes, I have indicated every instance in which the current was limited by space charge in Plaintiff's Exhibit No. 99 by a point enclosed by a circle. That is, there are three positions at 250 volts and four independent ones at around 200 volts. Some of these positions are repeated in several experiments. There are only five experiments recorded in that exhibit in which this sudden drop occurred, and thereafter the current was limited by space charge.

The first experiment I have marked by the letters a, and there were three points a_0, a_1 and a_2. In the lower right-hand corner of the sheet I indicated the page in the notes from which these points were taken, and I have also indicated the pressures at which the current values were taken.

If we look at the pressure values in the "a" experiment, we find that the pressure decreases, and this first point is the one about which I made my exception. For this point a_0, the current was fluctuating at least immediately before it was fluctuating. On Plaintiff's Exhibit No. 163, it is the point right—at the bottom of this zig-zag line. As I say, with that exception, for every other point that I have plotted here, whenever the pressure decreased, the current decreased. For instance, a_1 to a_2, the pressure decreased from .366 to .336, and as you notice the current has dropped from 5 to 4.5. In the b experiment, when the pressure dropped from .536 to .430, the current dropped from 3.2 to 3.0 milliamperes.

In the c experiment there are three points recorded. For the first one, the pressure is not recorded, but immediately before that point the pressure is .71, and after that, it was .51, so that for c_1, the pressure was somewhere between those two values.

Then as it dropped to .544, the current dropped from 3.1 to 3.0, and as the pressure dropped still further to .430, the current dropped to 2.9.

In the d experiment, there is only one point recorded.

In the e experiment, the pressure changed from .522 microns to .298 microns and the current dropped from 5 to 4.

Unfortunately, or at least, unfortunately for the purpose of testing whether or not the current would have dropped still further with a further decrease of pressure, there are no further decreases in pressure recorded at which current values were taken.

From my experience in these fields, I should say that the reason why the current stayed as constant as it did, was not because it would not have changed with a further change in pressure, but because the pressure did not go down any lower. An equilibrium value is reached in which there is just as much gas liberated from the walls as there is gas cleaned up, so that the pressure stays constant and consequently the current stays approximately constant.

If the pressures had been further decreased by pumping out gas, then I am confident that in this experiment the currents would have kept on decreasing for a considerable time until the pressure would have gotten so low that subsequent decreases in pressure would no longer have caused decreases in current.

The Court: Is this a suitable place for recess now?

Mr. Richmond: The diagram just referred to by the witness is offered in evidence as "Becker diagram for low current values of Sweetser, Auguest, 1912, notes."

(Received in evidence and marked "Defendant's Exhibit No. 295." *See Volume VI, Defendant's, Exhibits, page 1202.*)

Mr. Richmond: Your Honor, I will mention that this exhibit incorporates all the data in Exhibit J for Identification and other data.

By Mr. Richmond:

Q. 13. Dr. Becker, will you please go on and explain what you have recorded on that exhibit sheet, so far as you have not already done so in your explanation?

A. I have recorded all the space charge points that are to be found in Plaintiff's Exhibit No. 99. These are all of the points. There are no more in plaintiff's Exhibit No. 99.

Then I have enclosed a region in which I say:

> "If discharge had been substantially unaffected by positive ionization, the characteristic would have been within these bounds."

That means that if the current had actually been unaffected by the presence of gas, the points, instead of being where they actually are, would be somewhere between those two lines, the exact place can not be located, because I do not know what the exact distance between the filaments was, and the exact place would depend upon the distance between the filaments.

Q. 14. If there had been a pure electron discharge in this tube, with the recorded current values, would the current have fluctuated with changes in gas pressure?

A. You mean after the drop?

Q. 15. Yes, after the drop.

A. If, after the drop, the discharge had been a pure electron discharge, then the current should have remained constant as the gas pressure changed, and the very fact that it did not remain constant, shows that it was affected by positive ionization, because if there were no gas present, you could not have any positive ions.

Q. 16. Can you make some kind of an estimate of the values to which the current would have dropped further, with further improvement of the vacuum?

A. I think I have already given my estimate, and that is, it would have gone down to one-half to one-third in values that the current had at about four-tenths of a micron; that would depend somewhat upon the voltage and my estimates are based on the 250 volt value.

Q. 17. Then, when the current got down to that value, an improved vacuum, what would have happened with further improvement of the vacuum?

A. You mean after the pressure had gotten so low that the discharge would have been a pure electron discharge?

Q. 18. Yes.

A. Then a further decrease in the pressure would have no effect on the current.

Q. 19. Will you please give us the reasons for your estimate of the value that the current would have attained with further improvement in the vacuum?

A. Aside from the Sweetser note evidence, which I have given, and aside from my general experience with such types of discharge, I have specifically repeated this particular experiment, that is, I have duplicated as near as I could from the description given in the notes, the bulb which was used in August, 1912, and your Honor may be interested in seeing just how—this is as close a duplicate as I could make from the description in the notes (indicating to Court).

Q. 20. Describe the internal structure, Dr. Becker, so that it can easily be recognized.

A. In this particular case, the filaments are one-half inch apart and the plane of the filaments are parallel. The distance between the legs of the filament in this particular tube is a quarter of an inch. I have carefully examined the notes of Exhibit 99 to see whether there was anything said about the distance between the filaments or the distance between the legs of the filaments, and I can say positively that there is nothing mentioned in these notes concerning those distances. Consequently, of course, I could not duplicate the tube in that respect.

The first intimation I received of what that actual distance had been, was when Dr. Langmuir said that according to his recollection it was about half an inch. Now, it so happens that with this particular tube, the filaments are very close to one-half inch apart.

This bulb was put on a system very much the same as the system described here. The system consisted of liquid air trap, then a McLeod gauge to measure the pressures, and beyond that a mercury cut-off to disconnect the system from the pumps. Then I even went to the extent of blackening the bulb just as recorded in the notes; that is, whenever you send a discharge through nitrogen, after the discharge has run for some time, the bulb becomes discolored by a brown deposit. With this bulb, I first tried to see whether I could repeat as much of the experiment as is recorded that is, I introduced—after blackening the bulb—I introduced nitrogen gas—I should say that this system also had a means for introducing certain amounts of nitrogen, and the pressure could be adjusted by lowering the trap connecting it to the pump, pumping it out a little if necessary, and connecting it to the pump for a short time. In that way you could adjust the pressure to any desired value.

I adjusted the pressure of the nitrogen to five microns of pressure and I applied 250 volts between the two filaments, and I raised the filament temperature of the cathode—one of the filaments—to such a value that the current was about eighteen milliamperes. Then I watched to see what would happen, and just as they found, I found that the whole bulb was filled with a purple glow, and I also found that the pressure in the system decreased, and after a certain time when the pressure was in the neighborhood of four-tenths of a micron, the blue glow disappeared, and at the same time—the same instant—the current in the instrument which recorded the current, or which measured the current, would drop suddenly from perhaps sixteen or seventeen milliamperes down to, I think, in this case, down to four or five milliamperes. I have forgotten the exact amount.

Then, subsequent to that in some experiments, the pressure would keep on decreasing, and when the pressure decreased, the current decreased. In some other experiments, it sometimes happened that the pressure would increase, because that depended on the exact condition of the walls, just as it did in the exhibit. Sometimes under certain conditions, when the discharge was taking place, the pressure would increase; but in my case, whenever the pressure did increase, the current also increased. Then, after allowing the experiment to run for a certain time, it was approximately the same length of time—which was taken in Plaintiff's Exhibit No. 163, after the drop, after the drop, I went further than that, and I decreased the pressure by pumping the gas out. As soon as the pumps took hold—as soon as the mercury trap connecting the system to the pumps was lowered, so that I felt sure that the pressure was being decreased, just as soon as that happened, my instrument which recorded the current would drop, and then I would raise my mercury trap again, because I did not want to pump all the gas out at one shot. The current would stay quite steady, but there was a slow drift upward, the current would increase again, and when I measured my pressure, I found my pressure had increased. So after waiting for perhaps five to ten minutes for things to get about as steady as they were going to get, I connected my system to the pumps again and lowered the pressure still further, and repeated the same process. Then I plotted the value of the current in milliamperes against the pressure in microns, keeping the voltage between the filaments constant at 250 volts, and observed the points here plotted, and put in circles. You will notice that the points are in pairs. The lower one of these represents the condition of current versus pressure soon after the pumps had taken hold. Then, as the pressure increased, after the system had been shut off again from the pumps, it is to be noted that in every instance the current increased also.

Now, by connecting all of the points or as many of the points as possible by a smooth curve, one can see quite readily that at pressures in the neighborhood as low as even three-tenths of a micron, the currents were still at least twice as great as they were when the pressure was reduced to five one-hundredths of a micron, at which value the currents are quite approximately independent of the pressure.

Now, if the pressure had been higher than three-tenths of a micron, the currents would have been quite appreciably greater than they were at three-tenths, because in the neighborhood of three-tenths of a micron, the current is going up quite rapidly.

It is on this evidence among others, that I base my estimate of this factor of 2 to 3, as shown on the previous curve I presented, that is, Defendant's Exhibit No. 295. As I took a point at about 4.5 milliamperes and half of that would be about 2.25, it would be within the region there specified.

Mr. Richmond: The tube or bulb produced by the witness is offered in evidence as "Becker Approximate Duplicate of Sweetser's tube of August, 1912."

(Received in evidence and marked "Defendant's Exhibit No. 296." *See Volume VI, Defendant's Exhibits, page 1203.*)

Mr. Richmond: The diagram last produced by the witness is offered in evidence as "Becker Diagram for current pressure relation in tube Exhibit No. 296."

(Received in evidence and marked "Defendant's Exhibit No. 297." *See Volume VI, Defendant's Exhibits, page 1204.*)

Q. 20a. I notice that this tube, Defendant's Exhibit No. 296, has two little short wires in the glass on opposite sides. Please tell about those.

A. Those are two platinum wires sealed into the glass so as to make contact with this film on the inside. The purpose of those was to be able to determine the potential of the wall and it is on the basis of measurements made on those that I gave my previous description of changes in wall potential in the course of experiments, such as those on Plaintiff's Exhibit

No. 163. Now, during other tests, these were left floating. They were disconnected and they produced no result whatsoever different from what would happen if they were not there when they were disconnected; and even when you do have them connected in a circuit, if the potential that you apply to them is the same that they already have, it makes no difference. It is only when you apply different potentials that it changes the character of the results at all, and in most cases they were simply left floating.

Q. 21. Now, referring to that last current pressure diagram, Defendant's Exhibit No. 297, did you see any blue glow during the points that you have recorded on that diagram?

A. No. I did not see any blue glow.

Q. 22. Is that in accordance with your general experience?

A. It is with tungsten filaments. That is, tubes containing tungsten filaments. It is my experience that with currents of that magnitude and voltages of that magnitude and pressures of that magnitude, you can not see the blue glow.

Q. 23. Well, apart from what you saw, what is your belief as to the presence of blue glow at that time?

A. I am quite certain that there was some blue glow present.

Q. 24. How do you reconcile that with not seeing it?

A. Oh, very simply. It merely means that the eye is not sensitive enough as a detector; since whenever you have ionization in a tube, you must have the blue glow present, but the only reason that you do not see it is because your eye is not a sensitive enough detector, and also if the filament had been made of an oxide coated filament, such that the temperature had been a good deal lower, then, I am quite sure that even under those circumstances I could have seen blue glow.

You see the eye can not see a faint blue glow when it is contrasted with a very bright light. But you might very easily see that blue glow under other circumstances where there was no bright light around it, and I am quite sure that the amount of ionization under these circumstances would have been sufficient to have been visible had it not been for the bright tungsten filament.

However, I should say that if this experiment had been repeated with an oxide coated filament, the amount of blue glow right at the break would have been greatly diminished. Before the break there would have been a lot of blue glow, and after the break there would still have been some blue glow, but its amount would have been quite diminished, because there is a great deal less current than there was before, and consequently there is a great deal less ionization after the break than there was before the break.

Q. 25. Now, referring to these changes in current that occur after the break, what significance is there in a comparison of those changes with the magnitude of the change that you have referred to as the second stage of Defendant's Exhibit No. 163?

A. I think it is quite erroneous and misleading to compare changes in the third stage with the magnitude of the break of the second, because they are two different things. As I have explained before, the magnitude of the change during the second stage can be made large or small merely by changing the temperature; but the magnitude of the changes in the third stage depend on the changes in gas pressure, and do not in general depend on the temperature. So I think it is quite erroneous and misleading to try to compare these two things.

For example, in run No. 2, if the pressure had been decreased a lot, the change subsequent to the drop would have been of the same order, or perhaps even greater than the actual drop itself; whereas, in run No. 1, where the temperature was high, the subsequent changes after the drop, would not have been so very great, compared with the magnitude of the drop; and in another experiment, if the temperature of the filament in a run similar to run 1 had been even higher, the magnitude of the drop could have been made 100 times the changes subsequent to the drop.

Q. 26-27. To what extent are you familiar with Plaintiff's Exhibit No. 100, these Sweetser notes of November and December, 1912?

A. I have also carefully looked over these pages and have also familiarized myself with what they contain, and the type of experiments which they record, and the results derived therefrom.

Q. 28. Do you find any data in those notes exhibiting the dependence of the current on the cathode temperature in a two-electrode thermionic tube, and can you exhibit such data graphically?

A. Yes, I find very many curves showing the dependence of the current on the temperature of the cathode in fact.

Q. 29. You mean you find the curves, Dr. Becker?

A. No, I do not find curves in there, but I have plotted some curves, of which these are fairly representative.

Q. 30. You mean that you find the numerical data from which you have made these plots?

A. Yes, that is correct. I have only selected those temperatures which show the flat-topped region and have drawn just a sufficient amount of the region where the current is dependent upon the temperature to clearly indicate that at this stage, the currents were flat topped.

Now, this is a fairly representative compilation of flat-topped current temperature curves in Plaintiff's Exhibit No. 100 for hydrogen. I have been very careful to pick only such values or such experiments in which it was quite evident that the distance between the filaments was not changing, due to the application of a magnet, which Dr. Langmuir spoke about the other day. For all of the curves indicated here, the distance between the filaments is about 3 millimeters as recorded in those notes, so that they are all to be compared one with the other.

Now, when the current has the value representative of a flat-topped curve, that is, when the current say for the uppermost curve has this value or these values, the current is limited by space charge. In the region preceding that, the current is either limited by emission from the filament, or else it is in a transition region from about here to here (indicating), where it is neither limited by one alone or by the other, but limited to some extent by both. But in the flat-top part of the curve, the current is actually limited by space charge. Now that does not mean a pure electron space charge, that is a space charge composed solely of electrons, but it is composed of a mixed space charge. That is, there are electrons present and some positive ions. The positive ions that are present partially neutralize the negative electron space charge and as a result of that neutralization or partial neutralization of the space charge, the currents can be a good deal higher than they are in a vacuum. Of course, when the current is limited by space charge in these curves, the net result is still a negative space charge, but it does not have the value that it would have if the positive ions were not present.

Mr. Richmond: The diagram just produced by the witness is offered in evidence as "Becker current temperature diagrams for Hydrogen from Sweetser's notes for November and December, 1912."

(Received in evidence and marked "Defendant's Exhibit No. 298." *See Volume VI, Defendant's Exhibits, page 1205.*)

Q. 31. Referring to those diagrams, will you please tell us just how Richardson's law comes in there?

A. Why Richardson's law states how the current from the filament varies with the temperature of the filament and on these diagrams it hardly shows up at all. It would show up away to the left of these diagrams, away beyond at lower temperatures than here recorded. There as the temperature is lowered, the current keeps on decreasing. Actually due to the fact of the poisoning of the filament due to small amounts of water vapor, or oxygen, or some other gas, which would not be sufficient to affect the current in the space charge region, the currents in the region where they are limited by emission, are affected by these small quantities of impurities, and that is the reason why there is no regularity in this region, whereas there is perfect regularity in this region (indicates); that is, in the space charge region whenever the pressure increases, the current increases despite the fact that the voltage decreases.

The Court: Will you tell me that again?

The Witness: In the region where the currents are limited by space charge——

Q. 32. Dr. Becker, can you indicate the region in some way so that it can be identified when you speak of this region or that region?

A. In the flat-topped region, the current increases regularly as the pressure increases, despite the fact that the voltage is decreasing. If the pressure were constant and the voltage were decreasing, the current should decrease.

Q. 33. How do you get the bottom line of that diagram?

A. That lowest line of this diagram, the one that is dotted, is computed and shows what the current would have been if the voltage for curve No. 1, the lowest solid line curve, instead of being 180 volts, had been 99 volts.

Now, for the purpose of this computation, I have assumed that the 3/2 power law holds, and I have made a correction for the filament drop voltage; that is, in making this computation, I measured or computed my voltage from the middle of the cathode filament instead of from the negative end. In other words, I made the filament drop correction, which is perfectly well known, largely for accuracy. On the basis of that, I find that the current instead of being 66 units of current at 180 volts, would have been 26 units of current at 99 volts, when the pressure was one-tenth of a micron.

I think it is interesting to compare this value of the flat-topped current with the value of the flat-topped current for curve No. 6, which is also for 99 volts. The only difference between these two curves is the fact that for the higher one, the pressure is 7.2 microns; for the lowest one, the pressure is one-tenth of a micron, and yet the upper one is just as good a flat-topped curve as the lower one. But the current is 134 over 26 or 5.15 times as high as the current in a vacuum and still there is just as good a flat top as there was in a vacuum.

I might even state that, if, instead of having two filaments for cathode and anode, if the anode encloses the cathode, then even larger ratios are possible, and still the flat-topped emission curve is just as good for the high values of current and the high pressures of gas as it is in a perfect vacuum. In fact, all that is necessary to get a flat-topped curve is to have the current limited by space charge. That can be a mixed space charge, and does not have to be a pure electron space charge.

Q. 34. What is your opinion of the significance of such flat-topped current temperature curves, as tests for a pure electron discharge?

A. Well, I can hardly say that it is a good test. It is a very, very poor test. In fact, I would hardly give it the name of a test at all. It is in the same class as is the saying "all that glitters is not gold," in this sense, that while a pure electron discharge shows a flat-topped curve, you could have a discharge which is nothing like a pure electron discharge and still get a flat-topped curve. The flat-topped curve is a necessary condition for a pure electron discharge, but it is not at all a sufficient condition. That is, a pure electron discharge shows a flat-topped curve, but not every flat-topped curve discharge is a pure electron discharge, so that in answer to your question I would say if it is to be considered a test at all, it is certainly a very poor test.

Q. 35. I direct your attention to the flat-topped current temperature curves on pages 133 and 134 of Langmuir's Notebook 413, which is now Defendant's Exhibit No. 101. These notes were taken in the latter half of November, 1912. Do these flat tops give any indication of the purity of the electron discharge, when the corresponding readings were taken?

A. Just from the fact that they are flat topped, I can not draw any conclusion whatsoever as to whether the discharge was a pure electron discharge or not.

Q. 36. Referring to Exhibit No. 298 for hydrogen, which you produced recently, I notice that for each curve, there are two variables. The pressures vary from curve to curve, and the voltages vary from curve to curve. Can you make any comparison of these data on the basis of constant voltage, so that we can see the direct effect of pressure changes?

A. Yes. I think it is quite possible to do it. Just as before in getting curve 1a from curve 1, I assumed for the purposes of computation that the 3/2 power law held, and on the basis of that, computed what the current would have been at 99 volts. So here we can reduce all of these voltages to a common basis, and to be as accurate as possible, it is best to choose a value somewhere between the actual values; that is, between the values 99 and 180, such that if using the 3/2 power correction, there is some slight error in applying that law—as there will be, especially for the higher pressures—then the error will be quite small since the correction itself is small; that is, I chose a common voltage such that in no case will the correction be very large, and if there is a percentage error in the correction, the total error will be quite small. Thus, if the error in the correction is 10 per cent., let us say, and the correction itself amounts to 50 per cent., then the error in the result will only be a 5 per cent. error, that is, 10 per cent. of 50 per cent.

So that I have chosen 150 volts as a good intermediate value to which to reduce all the voltages, and for that voltage I have plotted the values of the current readings for hydrogen from these flat-topped curves.

Mr. Davis: May I interrupt? This from Exhibit No. 298?

Mr. Richmond: That is right, 298.

The Witness: This is 298. I have computed the values on the common basis of 150 volts for the current readings at various pressures, and I believe the scale on this new curve is so chosen that some of the points are left off. I think the highest ones are left off. The two highest curves on 298 are not plotted on the next curve, and also besides plotting these points, I have taken other points from the notes, which I could not plot on 298 without making 298 too mixed up. I have plotted them in the same way on the next curve. In other words, I have taken all the points for hydrogen that I could find in these notes, where I was sure that the distance between the filaments remain constant at about three millimeters, and have reduced all the current readings to what they would have been if the voltage had been 150 volts, and I then get the resultant curve marked: "Hydrogen: H_2."

Mr. Richmond: The curve just produced by the witness is offered in evidence as "Becker diagram for current pressure data in Exhibit No. 298, reduced to common voltage."

(Received in evidence and marked "Defendant's Exhibit No. 299." *See Volume VI, Defendant's Exhibits, page 1206.*)

The Witness: If I may, I should like to state that for all these points for hydrogen, the current is limited by space charge, but at the very low pressures this space charge is practically a pure electron space charge; that is, there are so few positive ions present that they do not affect substantially the current; but for the higher pressures the space charge was mixed, consisting of electrons and positives, and there the current is quite considerably affected by the presence of these positive ions. One can see from this curve that with this structure and a distance of three millimeters between the filaments and hydrogen gas present, one would have to reduce the pressure to perhaps six-tenths to eight-tenths of a micron before you get to the stage where a further decrease in pressure would no longer change the value of the current.

Q. 37. Your explanation so far for that sheet is related to the hydrogen curve, is it not, Dr. Becker? A. Yes, sir.

Q. 38. Please tell us about the curve marked "Nitrogen."

A. I proceeded in a similar manner for the data in Exhibit No. 100, in which nitrogen was present in the tube. There again I selected all the points for which I felt quite certain, first, that the current was actually limited by space charge; second, that the separation of the filaments was the same, namely, about three millimeters, and third, that there was nothing which would indicate that the data was suspicious or was not correct.

Q. 39. Why is the nitrogen curve steeper than the hydrogen curve?

A. There are several reasons, but the chief one is, as I think Dr. Langmuir has explained before, that the nitrogen is so much heavier than hydrogen that it moves much more slowly, and it traverses the space charge region around the cathode so much more slowly and stays there so much longer that its influence is felt for a longer time; and consequently its effect in neutralizing the electron space charge is considerably greater than that for hydrogen. In fact, it is readily seen that to get the same amount of neutralization of the space charge, it requires about five times as much hydrogen as it does nitrogen.

Q. 40. But have you purposely omitted any data in compiling the curve for nitrogen?

A. Oh, yes. There were two points which were purposely omitted, and the reason for those is apparent, when one looks at the pages on which the data for those two points occur. These are on pages 1403 in Plaintiff's Exhibit No. 100 down near the lower part of the page where appear these words: "Results doubtful plotted poorly."

I omitted the data in that neighborhood and did not plot the point which I could have gotten from that data on the curve sheet. These points would have corresponded to a reading of approximately seventy units of current, because when the temperature of the filament had gotten to the temperature corresponding to 9.7 volts, which I believe is 2325 degrees, the current did not increase when the voltage was increased to 10.5, which would correspond to a great deal higher temperature. So that the value of the current would have corresponded to seventy units, and the pressure which would have gone with that is .11; but I did not plot that because of the fact of this notation "Results doubtful."

Then, on the next page, on page 1404, there appears a similar notation, "Results doubtful," and I omitted that point for the same reason. Now, those are the only two points for which I found such a notation in this connection, so that those are the only two points which I purposely omitted. There might have been some other points which I overlooked but I am somewhat in doubt about that, as I was fairly careful to get all points which fulfilled all the conditions necessary to be a representative point.

Q. 41. I direct your attention to page 1565 in the Interference record, and ask you whether the data there shown are dependent on those pages of notes that are marked "Results doubtful"?

A. On the bottom of the page to which you have referred, that is, page 1565, there is a table in which the pressure in the first column is compared with, or at least is associated with the current readings, reduced to a common voltage of 100, just as I reduced it to 150.

The data here was reduced to 100, and the lowest two points in that table, that is, the ones that are most significant, are those very two points which I have pointed out in the notes, for which there appears the notation, "Results doubtful."

I might say that I think the choosing of 150 volts is a good deal better than the choosing of 100 volts, because of the error—the necessary errors that are known to exist at the higher gas pressures at which the 3/2 law does not hold. So by reducing to a common voltage, it is known you produce an error; but the larger the correction, the bigger the error will be, and the more likely you are to deduce erroneous conclusions from the data. So I think 150 volts which is an intermediate value, is a good deal better than 100 volts.

Q. 42. Please compare the electrode spacing for the Sweetser tube of November and December, 1912, with the spacing for the Sweetser tube of August, 1912.

A. In the Sweetser tube for November and December, 1912, the spacings vary, as Dr. Langmuir has pointed out, and it is quite obvious from looking through the notes that the distance between those filaments sometimes had one value and sometimes another value. I have found specifically mentioned values like 8 millimeters, another time 2½ millimeters; another time 3½ millimeters; but for the values which I have chosen, and the values for which most of the data in the notes was taken, it was about 3 millimeters.

So much for the distance in the November notes. In the August notes, I have very carefully examined those to find out what that distance was, and it is not mentioned.

As I said before, Dr. Langmuir I believe has testified that as far as he can remember, or from his recollection, that distance was about half an inch, and judging from my general experience I think that is not far from correct. That is, judging from the way the experiments went and the values of the currents—half an inch is not far from correct for the August work; whereas, most of the work in December had a filament separation of three millimeters.

Now, when that separation is specified as three millimeters, I think that probably that must refer to the tip or the loop of the filaments, actually very likely at the fastened end of the filaments the separation was probably half an inch, that is, judging from the fact that Dr. Langmuir testified that it was common practice to mount them on a common stem, and that distance was half an inch. Probably as I interpret the notes, when they say the distance is three millimeters, it means of the loop, and of course that would be the most determining region, that is, that would be the region where most of the electrons would come from, because it is the hottest part of the filament, and there is little emission from the cold region of the filament near the point where the filament is attached to the cold stem; so that three millimeters separation probably means a somewhat larger average separation, although not very much greater than three millimeters.

Q. 43. Now, this different spacing for the electrodes in the two tubes, causes what difference in the effect of the gas on the discharge currents?

A. Well, other things being the same, the bigger the distance between the filaments, the greater is the amount of gas, which is susceptible to ionization. Consequently, the greater the number of ions produced; consequently, the greater will be the reduction in the space charge; so that for a given pressure—for the same pressure—the further the filaments are apart, the greater will be the effect of gas.

Q. 44. Then, for a certain effect at a certain pressure in the December tube, what would be the comparative effect of the same pressure in the August tube?

A. If we take the figures to be three millimeters separation in the December experiments—at least for the parts to which I have referred—and twelve millimeters as the separation in the August experiments, then to a first approximation, the pressure should be divided by four to reduce the December pressures to equivalent pressures in August. To be specific, I refer to this last curve, Exhibit No. 299 for nitrogen, we see that with a separation in December of three millimeters, the pressure had to be reduced to something like, oh, let us say, 2/10 of a micron before it was substantially independent of the pressure.

Now, if that same pressure had been present in the August experiment, where the separation was four times as large, the number of ions produced, would have been approximately four times as great, or if we had wanted to get the same number of ions, we would have to reduce our pressure by a factor of four; and instead of having a pressure of 2/10 of a micron, we would have had four or five, one-hundredths of a micron before the current would have been substantially unaffected by changes in pressure. That figure of five one-hundredths of a micron agrees very well with what I actually found with the tube I have exhibited, for the value at which the current becomes substantially unaffected by positive ions; so that I can say that approximately the results from my tube with a separation of half an inch or twelve millimeters—half an inch is 12.5 millimeters—agrees with what one deduces from the December notes for the pressure below which further changes in pressure have no effect on the current. In both cases, the conclusion is that it is only when the pressure has been reduced to approximately five one-hundredths of a micron with a separation of half an inch between the filament that the current becomes substantially unaffected by positive ions.

Mr. Richmond: Direct examination closed.

U. S. District Court, Wilmington, Del.,
Thursday, 11th November, 1926,
10 o'clock A. M.

TWENTIETH DAY.

Before:
Hon. Hugh M. Morris,
U. S. District Judge.

Appearances as before.

Mr. Lunt: If the Court please, I would like to offer certain pages of the book by Richardson on the Emission of Electricity from Hot Bodies, published in 1916. This was the book referred to yesterday, and I offer in evidence pages 13 to 15 inclusive; pages 20 to 23 inclusive; pages 61 to 68 inclusive; pages 91 and 92; pages 117 and 118, and pages 128 to 138.

These are either referred to directly or indirectly in the testimony given by Professor Richardson on behalf of Arnold, and by Langmuir.

The Court: Have you inspected these pages?

Mr. Haight: No, sir, we have not.

The Court: Suppose they be admitted with leave to you to move to strike out any portions if you feel inclined to do so.

Mr. Haight: Your Honor would you rather have that course than their acceptance held in abeyance until we have had a chance to examine them?

The Court: It is not material. I was thinking the other way would get our exhibit numbers more nearly right, but probably not.

Mr. Haight: If it makes no difference to you I think I would rather adopt the latter course.

The Court: All right.

Mr. Lunt: I would also like to offer in evidence the patent to Langmuir, No. 1,558,437, of October 20, 1925. This appears as a part of Defendant's Exhibit No. 300, which was offered yesterday.

(Received in evidence and marked "Plaintiff's Exhibit No. 215." *See Volume IV, Plaintiff's Exhibits, page 313.*)

The Court: Now, the twenty patents, Mr. Richmond.

Mr. Richmond: Your Honor, twenty-two patents. In the first place, your Honor, if our opponents care to withdraw from the argument they have advanced heretofore that non-mention of high vacuum in Western Electric patents is significant, then I do not care to offer these twenty-two patents; but if they insist on that argument, based on the patents they have put in before, then I do ask to put in these twenty-two patents.

The Court: I have concluded that the slight confusion under which one or possibly two or more patents were put in in your case in chief in your defense, should not bar you from presenting your mass of evidence on this minor issue, and that in the exercise of discretion I shall permit you to present any evidence which might be deemed material to that issue. Consequently your patents are admitted, if they bear upon this issue.

Mr. Richmond: Very well, your Honor. Here is a list of the patent names and numbers. There are twenty-two of them; the exhibit numbers will run consecutively over them.

The Court: They will be admitted, but if counsel should later deem it advisable to withdraw from the record these patents, and there will be a withdrawal on the other side, either can do that at any time.

Mr. Davis: I merely make the objection that they are immaterial, the point being that each of them, so far as I have been able to examine them, speaks of an electron discharge apparatus. Whether we are right or wrong in thinking that be a proper term to explain this phenomenon is a matter of judgment in this case.

(The patent to E. F. W. Alexanderson, dated July 7, 1914, being No. 1,102,628, was received in evidence and marked "Defendant's Exhibit No. 302." *See Volume VI, Defendant's Exhibits, page 1233.*)

(The patent to W. C. White, dated August 22, 1916, No. 1,195,632, was received in evidence and marked "Defendant's Exhibit No. 303." *See Volume VI, Defendant's Exhibits, page 1241.*)

(The patent to I. Langmuir, dated July 23, 1918, No. 1,273,627, was received in evidence and marked "Defendant's Exhibit No. 304." *See Volume VI, Defendant's Exhibits, page 1246.*)

(The patent to W. C. White, dated March 25, 1919, No. 1,298,613, was received in evidence and marked "Defendant's Exhibit No. 305." *See Volume VI, Defendant's Exhibits, page 1251.*)

(The patent to I. Langmuir, dated April 22, 1919, being No. 1,301,279, was received in evidence and marked "Defendant's Exhibit No. 306." *See Volume VI, Defendant's Exhibits, page 1257.*)

(The patent to E. F. W. Alexanderson, dated August 12, 1919, being No. 1,313,042, was received in evidence and marked "Defendant's Exhibit No. 307." *See Volume VI, Defendant's Exhibits, page 1263.*)

(The patent to I. Langmuir, dated August 12, 1919, being No. Re 15,495, was received in evidence and marked "Defendant's Exhibit No. 308." *See Volume VI, Defendant's Exhibits, page 1267.*)

(The patent to A. N. Goldsmith, dated December 2, 1919, being No. 1,323,759, was received in evidence and marked "Defendant's Exhibit No. 309." *See Volume VI, Defendant's Exhibits, page 1271.*)

(The patent to A. N. Goldsmith, *et al.*, dated March 16, 1920, being No. 1,334,687, was received in evidence and marked "Defendant's Exhibit No. 310." *See Volume VI, Defendant's Exhibits, page 1276.*)

(The patent to E. F. W. Alexanderson, dated May 11, 1920, being No. 1,340,101, was received in evidence and marked "Defendant's Exhibit No. 311." *See Volume VI, Defendant's Exhibits, page 1280.*)

(The patent to E. F. W. Alexanderson, dated April 5, 1912, being No. 1,373,931, was received in evidence and marked "Defendant's Exhibit No. 312." *See Volume VI, Defendant's Exhibits, page 1285.*)

(The patent to J. H. Payne, Jr., dated December 13, 1921, being No. 1,400,235, was received in evidence and marked "Defendant's Exhibit No. 313." *See Volume VI, Defendant's Exhibits, page 1289.*)

(The patent to B. Bradbury, dated October 3, 1922, being No. 1,430,883, was received in evidence and marked "Defendant's Exhibit No. 314." *See Volume VI, Defendant's Exhibits, page 1293.*)

(The patent to H. H. Beverage, dated November 7, 1922, being No. 1,434,984, was received in evidence and marked "Defendant's Exhibit No. 315." *See Volume VI, Defendant's Exhibits, page 1297.*)

(The patent to H. H. Beverage, dated November 7, 1922, being No. 1,434,985, was received in evidence and marked "Defendant's Exhibit No. 316." *See Volume VI, Defendant's Exhibits, page 1303.*)

(The patent to B. Bradbury, dated January 23, 1923, being No. 1,443,209, was received in evidence and marked "Defendant's Exhibit No. 317." *See Volume VI, Defendant's Exhibits, page 1314.*)

(The patent to W. R. G. Baker, dated May 15, 1923, being No. 1,455,099, was received in evidence and marked "Defendant's Exhibit No. 318." (*See Volume VI, Defendant's Exhibits, page 131*[illegible])

(The patent to E. F. W. Alexanderson, dated August 28, 1923, being No. 1,466,263, was received in evidence and marked "Defendant's Exhibit No. 319." *See Volume VI, Defendant's Exhibits, page 1321.*)

(The patent to O. C. Traver, dated October 9, 1923, being No. 1,470,582, was received in evidence and marked "Defendant's Exhibit No. 320." *See Volume VI, Defendant's Exhibits, page 1325.*)

(The patent to E. F. W. Alexanderson, dated April 22, 1923, being No. 1,491,372, was received in evidence and marked "Defendant's Exhibit No. 321." *See Volume VI, Defendant's Exhibits, page 1331.*)

(The patent to W. C. White, dated June 30, 1925, being No. 1,544,202, was received in evidence and marked "Defendant's Exhibit No. 322." *See Volume VI, Defendant's Exhibits, page 1337.*)

(The patent to A. W. Hull, dated July 21, 1925, being No. 1,547,153, was received in evidence and marked "Defendant's Exhibit No. 323." *See Volume VI, Defendant's Exhibits, page 1341.*)

JOSEPH A. BECKER, resumes the stand.

CROSS-EXAMINATION.

By MR. DAVIS:

XQ. 45. In the first stage, using the language, Doctor, which you used yesterday, of the phenomenon which was observed by Dr. Langmuir and Mr. Sweetser in August, 1912, you remember you divided that into three stages. I am thinking now of the first stage. I understood you to testify that in that stage the current was limited only by the emission from the cathode and that the bulb was full of blue glow; is that correct?

A. I believe I made a slight provision. I did not say that it "was limited only," I said "practically," and that it is correct.

XQ. 46. As a practical matter it is limited only by emission?

A. Yes. I want to make sure that I am not misinterpreted.

XQ. 47. The other factors were negligible in your judgment?

A. Yes, and the bulb was filled with blue glow.

XQ. 48. What part of the bulb was filled with blue glow?

A. At the pressures of approximately five microns or down to three microns practically the whole bulb. Then as the pressure gets down lower——

XQ. 49. We are talking about the first stage.

A. Yes, I am talking about the first stage.

XQ. 50. All right.

A. In the beginning of that stage the whole bulb is filled with blue glow. Then as you approach near to the second stage, where the glow is going to drop in, you can actually see that the glow is disappearing. I can illustrate that if I may have the bulb. I have now Defendant's Exhibit 297. When the pressures are fairly high the whole bulb, including from the top of the bulb to the lower part of the bulb, is filled with a blue or purple glow. Then just before, say perhaps a minute or two before the glow is going to drop in you can actually see the glow disappearing from the upper portion of the bulb and also at the same time you can begin to see that it is less pronounced in the neighborhood of the glass walls. Then all of a sudden it disappears as far as the eye is concerned.

XQ. 51. That is, you get a dark space around the walls?

A. At first there is quite an appreciable dark space up in this partial portion, the portion of the bulb containing the stem and you can also see it separate to some extent from the walls of the glass, although that is not very pronounced. It might be partly an illusion, because in looking through the middle of the bulb you have a deeper path but it is quite pronounced in the stem portion that the blue glow is certainly much fainter.

XQ. 52. And in that first stage the space charge is completely neutralized throughout the whole bulb?

A. I do not know just what you would mean by the space charge being in certain parts of the bulb, I do not think it is correct to differentiate space charge in this part of the bulb. If you mean the density of charge in different places then I can talk about it.

XQ. 53. I mean the density of charge established by Poisson's equation?

A. If you mean to say that there is no space charge in any portion of the bulb, in other words, that every little portion of the bulb is electrically neutral, I do not know that I would agree with you perfectly. I do not know that I have any evidence of that. What is true is that the current is not limited in any sense by space charge.

XQ. 54. Is it not true that all of the gas in the bulb is at substantially the same potential in that stage?

A. I am not so sure that that is true. I think it is pretty nearly correct. I have never personally measured what the potential is in all parts of the bulb.

XQ. 55. But you know from a consideration of the matter that that statement is substantially true?

A. I think so.

XQ. 56. So that there is no field of any magnitude anywhere in the bulb?

A. Oh, no. Of course not. There is quite a big field in the neighborhood of the cathode. In certain stages there is a big field in the neighborhood of the anode and there is probably a field to some extent in the neighborhood of the glass walls.

XQ. 57. Let us take these one at a time. Of course there is a field in the neighborhood of the anode?

A. I think under some cases there is, yes.

XQ. 58. Is there a field in the neighborhood of the cathode?

A. Oh, yes, there is always an intense field in the neighborhood of the cathode.

XQ. 59. How far out does that extend?

A. Not very far.

XQ. 60. It is a matter of millimeters?

A. Oh, I do not know.

XQ. 61. I am talking about these high pressures.

A. My impression is that it is less than a millimeter.

XQ. 62. So that the substantial drop of potential in that tube is concentrated in a very small volume outside of the cathode?

A. Will you please say that again?

XQ. 63. The substantial drop of potential in the tube is concentrated in a very small volume surrounding the cathode?

A. Yes. Quite a considerable proportion of the difference of potential between the two filaments takes place in the immediate neighborhood of the cathode.

XQ. 64. That is the old-fashioned cathode drop, is it not?

A. It is analogous to it.

XQ. 65. I do not want to be too accurate or too scientific, but that is a rough way of looking at it and a fairly accurate way?

A. Yes.

XQ. 66. As a matter of practice all the potential is in the cathode drop?

A. I did not say so.

XQ. 67. I am asking you.

A. I think under some circumstances there is quite an anode drop.

XQ. 68. Under what circumstances?

A. I do not know that I can tell you exactly, Mr. Davis, but I know that sometimes there is quite an appreciable anode drop too, I mean right in the neighborhood of the anode there will be a drop.

XQ. 69. That would be very close to the anode?

A. I am under the impression that it is, yes.

XQ. 70. So that the bulk of the tube is electrically pretty neutral?

A. If interpreted electrically pretty neutral in the sense that the difference of potential——

XQ. 71. From point to point?

A. From point to point where your points are not near the anode or cathode, or too near to the glass walls, then I will agree in that sense. I should modify that to this extent, that when your pressures get down low——

XQ. 72. We are talking about ten or fifteen microns.

A. Then I will agree with you.

XQ. 73. Let us take the simple thing first. The walls of that stage are at anode potential?

A. Pretty nearly.

XQ. 74. Not quite?

A. I do not know. At ten or fifteen microns I do not know how much difference there would be but they would be very close to anode potential.

XQ. 75. How do you know that?

A. I know that because in working with pressures of five microns and in this bulb I have measured that potential on the glass walls and I found that it is not very far different from the anode potential.

XQ. 76. Which way does it differ?

A. It is less in the case in which I measured it, less than the anode potential.

XQ. 77. In five microns the wall is slightly negative with respect to the anode?

A. Yes, if the cathode is at zero the bulb might be at 145 volts positive.

XQ. 78. Now, an electron emerging from the cathode has to pass through this steep potential gradient surrounding the cathode?

A. Yes, sir.

XQ. 79. And when it has gotten through that it shoots through it, does it not, like a projectile?

A. Shoots through what?

XQ. 80. Through this space surrounding the cathode?

A. It does not shoot through it after it has gotten through.

XQ. 81. Perhaps I did not make my question clear. I am trying to see what would happen to an electron that was active enough to get through this cathode space. It would shoot out in straight lines, would it not? You need not answer that question because I do not think it is very well framed. How did the electrons get through this cathode space? Let us begin from the beginning.

A. If an electron is once liberated from the hot filament, that means if it gets to a distance of one-one hundred thousandths of a centimeter away from the surface of the tungsten filament, it is then practically free from the surface. It is then subjected to this intense field which surrounds the filament and is accelerated by that field.

XQ. 82. And that field is a very large part of the 100 or 200 volts that is on the tube?

A. That is the thing I have answered before. Under some circumstances it is a large part.

XQ. 83. I want to make it clear that here you have in this kind of a discharge a little shell surrounding the cathode which the witness says is only a millimeter thick and in that shell is concentrated most of the potential of the tube. The electron shoots through that, is that right?

A. I would like to put things in my own way, Mr. Davis.

XQ. 84. Please do.

A. I said that when the electron is liberated from the filament it is accelerated by this field. If you want to call that shooting through the field, well and good. Then it gets into this region where there is practically no field and when there is no field there is no force acting on it and it keeps on moving until it hits something or until it goes into a region where the fields again act upon it. So that now at these high pressures after it has gone through this cathode drop, the chances are it will hit something before it gets to the glass wall.

XQ. 85. When it comes out of this narrow space, this thin space around the cathode, it comes out at a pretty high velocity?

A. Yes, at a velocity corresponding to the equivalent voltage drop.

XQ. 86. And that means it comes out considerably above the velocity corresponding to ionization?

A. If that drop is greater than the ionization potential, yes.

XQ. 87. It is in the case we are talking about?

A. It is in case you have 150 volts on the other filament.

XQ. 88. So that this electron can ionize almost anywhere in its path, can it not?

A. Provided it hits something.

XQ. 89. It has velocity enough to ionize?

A. It has energy enough, yes.

XQ. 90. So that any collision between that electron and a molecule is capable of producing ionization unless the collision occurs in that thin space around the cathode; is that right?

A. I should say that even in that thin space around the cathode there are parts of that thin space where it has sufficient energy.

XQ. 91. What happens to these ions when they are formed?

A. That depends on a good many circumstances.

XQ. 92. They are not in a very strong field, are they?

A. No, and that is just why it depends on a good many circumstances, on just accidental velocities that they happen to have at the instant at which they are ionized.

XQ. 93. There is nothing that amounts to anything to pull them away?

A. I would not say that there is nothing that amounts to anything. The forces are small.

XQ. 94. The forces acting to pull them away are small?

A. Yes.

XQ. 95. And therefore they sort of lie around until something happens to them?

A. I would not say that.

XQ. 96. What do they do?

A. Remember that atoms even at room temperature are far from lying around, they are travelling with speeds of the order of a mile a second.

XQ. 97. I might say wandering around.

A. If you want to say that speeds corresponding to a mile a second are wandering around then they do wander around, yes.

XQ. 98. They are very slow in getting out of the space, are they not, as compared to what they would be in a high vacuum tube?

A. I would not say that at all.

XQ. 99. Why would you not say that?

A. It depends entirely on the fields acting on it. In a high vacuum tube they might have very strong field pulling them one way or the other and if they have strong fields pulling them they move pretty rapidly.

XQ. 100. That is what I was trying to get at. In the high vacuum tube there is a tendency to remove the ions which pulls them toward the cathode?

A. Provided there is a strong field which pulls the ion toward the cathode.

XQ. 101. There is generally in a high vacuum tube?

A. Not always. It might pull them towards something else.

XQ. 102. But the distribution of potential in the two cases is different, in one case you have a distribution potential in the high vacuum tube across the tube from anode to cathode with a relatively smooth drop of potential, whereas, in the case of the tubes we are considering the drop is around the cathode?

A. I do not like the term you used in a high vacuum tube. You can have this different potential distribution even though your tube is not a high vacuum tube, as for example, after the drop, I would not call the tube a high vacuum tube, but yet the potential distribution is different from what it was before the drop.

XQ. 103. What actually does happen in this first stage with these ions that are formed?

A. They move and as I said the exact thing that happens to them depends on circumstances. If for example you take this standard as one filament, and that standard as the other filament, and this room as a bulb, and if the ion happens to be here, if it happens to go in that direction, it would keep on going in that direction until it got to some region where these small forces which are not entirely negligible would deviate it from its path.

XQ. 104. It can go to the glass walls?

A. Provided that the glass walls are at a potential which will not repel them.

XQ. 105. And it can go to the anode?

A. No, it cannot go to the anode.

XQ. 106. It can go to the cathode?

A. Yes, sir, it can go to the cathode.

XQ. 107. Does the charge on the walls of the bulb in this first stage substantially influence the flow of current through the tube?

A. Do you mean by that that if I could change the potential of the walls——

XQ. 108. Let us ask if the actual charge does seriously influence it. You said the walls I think were about anode potential perhaps five volts negative. Does that fact substantially influence the flow of current through this tube?

A. If by that you mean the current from the cathode to the anode I should say not. I could change the wall potential from let us say 135 volts which it might have to 125 and that would vary little if at all change the current from the cathode to the anode.

XQ. 109. And if you should put a grid in the tube, the grid would be ineffective, would it not?

A. Not unless it were placed in a very peculiar position; not unless it were placed very close to the cathode or in a critical region. If the grid were placed at considerable distance from either the cathode or the anode and not right straight in between them, then what you say is true.

XQ. 110. That is, it would be ineffective?

A. Quite ineffective. All this I take it is limited to quite high pressures.

XQ. 111. We are talking about this first stage.

A. But there are parts of the first stage, towards the end of the first stage, for which not everything that I have answered to your questions is quite true.

XQ. 112. I understood you to be talking about something like ten microns.

A. Yes, then everything I said is true.

XQ. 113. Are these things true at five microns what we have been talking about?

A. Yes, at five microns it is still all quite true.

XQ. 114. Now, let us turn our attention to what you call stage 3. In that stage there is space charge all through the bulb, modified, as you put it, the other day, by positive ions; is that your view?

A. I do not like the expression "space charge in all parts of the bulb" because I have not studied it and I do not know whether very many people have studied just what the density of charge is in all parts of a bulb like this. The current is limited by space charge.

XQ. 115. So that there must be space charge somewhere between the anode and cathode anyway?

A. Yes.

XQ. 116. You said that in this stage, if I understood you correctly, the distance between the anode and the cathode had an effect on the current although such distance did not have such substantial effect in the first stage. Will you explain why it has an effect in the third stage, that is why the distance from anode to cathode affects the current?

A. The reason is very similar to the reason why distance between the plates in a parallel plate case has an effect on the current. It is for quite exactly similar reasons.

XQ. 117. In this stage you said that there was a charge on the bulb of a few volts minus with respect to the negative end of the filament; is that right?

A. Are you sure I said that?

XQ. 118. I am not sure. I forget what you did say.

A. If I remember correctly I did not say that. I said immediately after the drop when the pressures were of the order of .5 microns that the potential of the walls of the bulb were several volts positive with respect to the negative end of the filament.

XQ. 119. Thank you, Doctor. I beg your pardon. Did you ascertain that by experiment?

A. Yes, sir.

XQ. 120. How did you do it?

A. Very simple. By means of these platinum lead-in wires.

The Court: You are referring now to what exhibit?

The Witness: Thank you. I am referring to Defendant's Exhibit 297.

A. (Continued.) By means of platinum lead-in wires on the sides of the bulb I can apply various potentials to the inside wall. Now, if the potential applied to those wires is different than the potential at which the wires are, or tend to be, then a current will flow in this subsidiary circuit or auxiliary circuit. If, however, I applied a potential with respect to the negative end of the filament which is the same potential as these points are with respect to the negative end of the filament, then nothing happens at all in this auxiliary circuit.

So that I merely vary the potential applied to these as measured from the negative end of the filament until no current flows in that circuit. That is one way of telling what the potential of those points is when they are floating.

Another criterion is to see whether or not when you apply a potential there is a change in the current flowing from the cathode to the anode. When you apply a potential to this wall which is just equal to the potential, at which it tends to be by itself, then there is no change. This second method is not as sensitive and not as convenient as the first. I actually applied both methods and found the first one to be more convenient and used it.

XQ. 121. And you did find that applying potential to the walls of the bulb different from the potential at which they happened to be at the time, changed the current flowing in the main circuit of the tube?

A. Yes, sir. If I changed that potential sufficiently I could change the current flowing from the cathode to the anode.

XQ. 122. That was sort of a grid action?

A. Something like a grid action.

XQ. 123. I suppose you could have put a grid into that tube at this stage and varied the current?

A. Certainly.

XQ. 124. Have you any quantitative data as to the effect of these various potentials applied to the walls on the flow of current?

A. When I did the experiment I had quantitative data.

XQ. 125. You have not it here?

A. No, sir.

XQ. 126. Perhaps you could remember in a general way what the order of magnitude of the effect was?

A. I think in a general way I can, yes.

XQ. 127. Suppose you give it to us?

A. Just what?

XQ. 128. I want to see——

A. Can you tell me more definitely what you want me to give?

By Mr. Davis:

XQ. 129. Let us assume a current of four milliamperes in a tube. Is that reasonable?

A. Yes.

XQ. 130. At the beginning of stage 3?

A. You mean right after the drop or soon after the drop?

XQ. 131. Soon after the drop.

A. All right.

XQ. 132. And there you have the walls charged to about plus 4 normally?

A. Yes.

XQ. 133. Suppose you change that to zero, what would happen?

A. In that case the current between the cathode and anode might change to something like 3½ to 3 from 4. I take it you assumed a potential between filament and grid of something like 200.

XQ. 134. Yes, that is what I mean.

A. That would make a difference.

XQ. 135. I was trying to make the conditions as near as we can to the experiments that Dr. Langmuir carried out. There were 200 to 250 volts across the tube in these experiments, as I remember it, and if you made the wall potential plus 8, instead of plus 4, it would roughly do what to the current?

A. A very interesting thing would happen when you do that, Mr. Davis, if I may change your plus 8 a little bit, will that be convenient?

XQ. 136. If you will.

A. If in that stage you suddenly change the wall potential from plus 4, let us say to plus 16, it can then happen that the blue glow will come right out again, thus showing that the blue glow is dependent upon the wall potential. I have done an experiment just similar to that, in fact, I did an experiment something like this: I had my potential at such a value that the blue glow was not present, then I suddenly increased the potential on the wall to something like 12 volts, and my blue glow appeared.

XQ. 137. And this thing happened about 16 volts, did it?

A. Which thing?

XQ. 138. This phenomenon you have mentioned, the reappearance of blue glow?

A. The thing I remember clearly is that I suddenly changed the potential by 12 volts. Now, if I changed it by more than 12 volts, the same thing would have happened. If I changed it at only four volts I doubt very much whether the blue glow would have appeared.

XQ. 139. And when you get it into this condition by putting this plus—was the tube or not back in stage one, as a practical matter?

A. If the blue glow appeared, or when the blue glow appeared, the current from cathode to anode went up and the current was limited by the filament temperature, yes, so that I should say it had all the characteristics present in stage one.

XQ. 140. Now, in this stage three, the distribution of potential around the cathode is what? That is, you had a very heavy accelerating field around the cathode in stage one?

A. Yes.

XQ. 141. What did you have in stage three?

A. There is still quite an accelerating potential in stage 3. It is not as intense as in stage 1, since it is not so concentrated, but the biggest part of the potential drop is still at the cathode.

XQ. 142. Then why does not the tube saturate immediately?

A. Have you finished your question?

XQ. 143. Yes.

A. Why does not the tube saturate immediately?

XQ. 144. Yes.

A. Do you mean by that why is not the current limited by the filament temperature?

XQ. 145. Yes.

A. Because it is limited by space charge.

XQ. 146. But you have an accelerating field tending to pull these electrons out, and why don't they come out?

A. I beg your pardon, Mr. Davis. When the current is limited by space charge, right at the cathode, right at the very surface of the cathode——

XQ. 147. That is what I was inquiring about.

A. There the field is very small and probably is in the negative direction; that is, it tends to drive electrons back into the filament right at the cathode. By that I mean something like one-hundredth of a centimeter or perhaps even less. Then as soon as you get outside of that region—and that was what I was referring to before—my statement is correct; only I want to modify it to take account of what you evidently had in mind.

XQ. 148. I was thinking of the space immediately surrounding the cathode, Doctor, and there you have a retarding field rather than an accelerating?

A. That is defining "immediately" to be something of the order of one-hundredths or thousandths of a centimeter.

XQ. 149. Well, I was thinking perhaps inaccurately, but to the best of the ability I had, of this same space which in the experiment No. 1 was a strong accelerating field, which I think you said was something less than a millimeter. Now, this same space, or part of it at least, has become the retarding field, when you change conditions to those of No. 3?

A. That is, that part which is very close to the cathode, yes, but a considerable part of that, the remainder of it, still has quite an accelerating field.

XQ. 150. How do the electrons get through this retarding field?

A. Chiefly because of initial velocity due to the fact that the filament is at a high temperature.

XQ. 151. So it is only the more energetic and active ones that manage to get through, is that it?

A. Yes, but remember these retarding fields you are now speaking of are very small. They are fractions of a volt.

XQ. 152. So are the initial velocities, are they not?

A. The initial velocities are also small, so that the things are comparable. They do not need very much energy to overcome the opposing field.

XQ. 153. Now, let us imagine an electron which is active enough to get through this field. What does it do?

A. After it passes through the opposing field, it enters the accelerating field and is accelerated, and moves faster and faster. It does what any body subjected to force does.

XQ. 154. I was thinking of the shape of the path, Doctor. I think you told us that in the first stage, the No. 1 phenomena, the electrons when they got through this space, this dark space, shot out normally into straight lines?

A. I said a little more than that.

XQ. 155. What did you say?

A. I said a little more than that.

XQ. 156. Well, you said that much; you said also that they might hit something; but I mean until they hit something, you gave us the impression they shot out into straight lines?

A. Or until they came to a region where they were subjected to other forces.

XQ. 157. I quite agree, Doctor, you said that very carefully, but I was trying to shorten it, that is all.

A. All right.

XQ. 158. In this third stage, do they shoot out in straight lines after they get through this first field?

A. It depends. If they are not subjected to forces which are perpendicular to the direction of motion, they keep right on moving in a straight line; but when they get to a region where those forces are not in the direction of motion, then they change their path.

XQ. 159. Let us think of an electron which is active enough to get through this first space, and which is going to form part of the current that flows across the tube, which I suppose means it is going to get to the anode. What is the typical path of such an electron?

A. About the simplest way to say it, is the typical path is a curved path.

XQ. 160. What kind of a curve?

A. It depends on so many different things. I can say one path is a spiral, a sort of spiral.

XQ. 161. A sort of spiral around the anode?

A. I would not say that that was necessarily always so.

XQ. 162. Oh, no, but the typical case?

A, It depends on the gas pressure to some extent, if it hits a gas molecule and ionizes it, its velocity is considerably decreased, and perhaps brought to a very small value, and then it starts to follow the lines of force from there on, and its chance of hitting the anode is somewhat greater.

XQ. 163. But it is a matter of chance hitting the anode first time, is it not?

A. At the first time, I think so.

XQ. 164. And if it misses the anode the first time, what would it do?

A. That depends on circumstances again. It depends on just what region of this third stage you are talking about.

XQ. 165. It is something like a comet coming into the solar system, is it not?

A. Well, if you do not stress the "something like," too much, I will agree with you.

XQ. 166. That comet may be trapped and rotate in an orbit around the sun, may it not?

A. Not unless its energy is changed.

XQ. 167. That may well happen, may it not?

A. It may or may not. I would not say. It may well happen if it hits something or there are resisting forces which decrease the energy. As a matter of fact, most comets, I think come in and go out, and I think it is a rather rare occasion——

XQ. 168. They go back, don't they?

A. Some do and some don't. Those that do, already have lost some of their original energy, and unless they lose their energy, they keep on going.

XQ. 169. And most comets do not hit the sun?

A. I am not well versed enough in cosmology to say whether they do or do not.

XQ. 170. Most electrons do not hit the anode the first time?

A. Most of those that start from the cathode?

XQ. 171. Yes.

A. I do not think so.

XQ. 172. I do not think the answer is quite clear. Do you mean you agree or disagree?

A. I am inclined to agree with you. I have not analyzed that. I have not thought of that specific question before.

XQ. 173. And those that do not hit the anode the first time will either be thrown out of the field of the anode, or will circulate around the anode in some sort of complex way; is not that right?

A. They will certainly not circulate indefinitely.

XQ. 174. No, but for a while?

A. For a while, yes.

XQ. 175. And ultimately they will fall into the anode, will they?

A. Some will and some won't.

XQ. 176. So that there will be a pretty strong field around that anode, won't there?

A. Will you read that? (Question repeated as recorded.) I do not see how you can draw that conclusion from what has gone before. If you ask me whether there is or not, that is a different matter.

XQ. 177. I will ask you whether there is, Doctor?

A. Yes, there is a field and a strong field, and especially—that depends on the shape of the anode—if it is in the form of a filament, there will a strong field. There again, it depends on circumstances.

XQ. 178. We are talking about a typical case, Doctor, of course, I understand.

A. There are so many typical cases. If you have a high vacuum, such that, there are no ion effects, and if your anode is in the form of a filament, there is a high potential gradient in the neighborhood of the anode.

XQ. 179. There is quite a high potential in the neighborhood of the anode in what you call the third stage, is there not?

A. Certainly in a high vacuum stage, and very likely also throughout the whole stage.

XQ. 180. Now, these electrons coming out of the cathode which describe these paths, which we have been trying to analyze a little, start out rather slowly, don't they, as compared, for instance, to the way they come out of the cathode space in the first stage?

A. If you mean that when they are at a distance of one millimeter from the cathode, their velocity is smaller than it was in the first stage, then I would say yes; but that velocity is not so terribly small, even when they are only one millimeter away.

XQ. 181. In the first stage, when they are one millimeter away from the cathode, they had a velocity corresponding to a very substantial fraction of the voltage across the tube, don't they?

A. Yes.

XQ. 182. In this third stage, they have no such velocity as that, have they?

A. I would say they had quite a substantial, yes. When they are one millimeter away, my estimate would be that they would have perhaps one-quarter of the velocity corresponding to the total drop.

XQ. 183. They have been through a retarding field?

A. Yes, but that retarding field, as I said before, is present only in a small region very close to the filament, and beyond that you soon get into an accelerating field and——

XQ. 184. But you are going to get a quarter of the whole voltage on the tube in a millimeter?

A. Without further calculations, yes, I think that is quite right.

XQ. 185. In spite of the fact you have a good deal of a drop around the anode?

A. Remember, I did not say that you had a very large part of the total drop around the anode. You have a considerable, as most of the drop is still concentrated in the neighborhood of the two filaments.

XQ. 186. In your answer to Q. 10, Doctor, you said on page 1795, that with a very special structure of tube, it might be possible to have the walls of the tube become negative immediately after the drop, corresponding to the second stage. Please tell me what kind of structure you had in mind when you referred to this special structure?

A. Could I see that, please?

XQ. 187. Surely (handing volume of testimony).

A. Did you say page 1795? I do not see that particular reference on that page, Mr. Davis.

XQ. 188. Perhaps you can find the place better than I can, Doctor.

A. I would rather prefer to put it the way I did, exactly in the exact way I put it, if you do not mind.

XQ. 189. Please do. I may have summarized it wrong.

A. What I actually said on page 1796 was:

> "If you modify the type of structure sufficient to bring out just certain points, I would not dare say that it was impossible to have the wall negative immediately after the drop, but from my experience I should say that one would have to take a very special structure to do that. And in general the walls are positive, slightly positive, immediately after the drop, and they do not become negative until the pressure is decreased considerably. But the most important thing I think is that just before and just after the occurrence of the sudden drop, the wall potentials undergo a sudden change."

I do not think when I said that, I had any special one in mind. I just wanted to make clear that the general thing was that the walls were positive immediately after the drop.

XQ. 190. Now, on the next page 1796, in answer to Q. 11a, you said something about reducing the current or the pressure rather by a factor of 8 or 10, or it might be 5, in the particular type of structure, and the current being two or three times lower than the value in stage 3, if I understood you correctly, Doctor?

A. What is your question, Mr. Davis?

XQ. 191. Whether I understood you correctly, that is all.

A. I think the best thing if you want me to, is to repeat substantially what I said then.

XQ. 192. I do not want to trouble you to do that. Did you speak of this reduction of potential as being necessary to transform the conditions of stage three into a condition of pure electron discharge, in which the positive ions were playing a non-substantial part, did you not?

A. What I said was that immediately after the drop, the currents had a certain value; that if you then changed the pressure by a factor of, let us say, 8, the value of the current would then decrease to one-half or one-third the value that it had soon after the drop.

XQ. 193. You distinguish, at least I understood you to distinguish, between the conditions in stage 3, which you define as a condition in which the current is limited by space charge, substantially affected by ionization, and the condition which would arise if you had this still higher vacuum, which I understood you to say was the condition where the current was limited by space charge, not substantially affected by ionization; is that true?

A. That is the general characterization of stage 3. The current is limited by space charge, but this space charge may be a mixed space charge, and it is only when the pressure has been decreased considerably, that you arrive at the place where the space charge is substantially unaffected by positive ionization.

XQ. 194. What do you mean by "space charge substantially unaffected by positive ionization"?

A. I mean that the space charge is a pure electron space charge in the sense that the number of positive ions which are inevitably present—unless you have a perfect vacuum, which it is impossible to get—that these positive ions play an unsubstantial part; their number is so small that they do not affect substantially the current flow.

XQ. 195. It is the effect rather than the number you are interested in, is it not?

A. Well, I think what I said, speaks for itself.

XQ. 196. Now, if you have a tube containing gas and pass current through it, you get light, a glow in the tube there frequently, don't you?

A. Oh, I would like to be more definite, Mr. Davis——

XQ. 197. I am just trying to get at this thing, what we call blue glow. If the gas pressure is pretty heavy, the blue glow is apt to be purple, is it not?

A. It depends on the gas.

XQ. 198. With nitrogen, it is purple. Now, if you reduce the pressure, continuing to pass the current through the tube, that purple turns into a blue, does it not?

A. I do not know that I would say that. That depends on your exact shade.

XQ. 199. It changes color?

A. I do not know that I would even say, that it changes color.

XQ. 200. I see so many references to pale blue haze, and in tubes of a higher current, I see so many references to red and purple haze, I thought there was a tendency to change color?

A. I do not see what difference it makes, whether the exact tint is blue or purple; I think it would depend on the person looking at it, on his judgment.

THE COURT: May we take our recess today at eleven o'clock.

(After a short recess.)

By MR. DAVIS:

XQ. 201. Now, in your testimony on direct you testified about some blue haze that you could not see, for instance, at Q. 24, do you remember that?

A. I remember about it.

XQ. 202. What color was that blue haze?

A. If you could not see it you could not very well say what color it was.

Mr. Davis: That is all, if your Honor please.

Re-Direct Examination.

By Mr. Richmond:

RDQ. 203. If directly after the drop of the current, which you have referred to as the second stage, you had then without changing the pressure, imposed a change on the voltage of the wall so as to bring it down to the voltage corresponding to extreme high vacuum, how would that imposed change on the wall voltage have affected the current at that stage?

A. I think it would have had a grid action effect or I think that action would have been quite small—this is just an estimate—I think it might have made one-tenth the change that actually took place by reducing the pressure to such a stage that the wall potentials came to minus 2.

Mr. Richmond: That is all.

Re-Cross-Examination.

By Mr. Davis:

RXQ. 204. How do you know that?

A. I base my answer on this: I do not think I ever did what Mr. Richmond's question implied, but I did this, after the pressure was reduced and after the wall had come to a slightly negative potential with respect to the negative end of the filament, I then applied purposely more negative potentials and as I remember it I applied negative potentials fully as great as the difference between the wall potential at the initial part of stage 3, that is, the beginning of stage 3, and the wall potential at the end of stage 3 in the high vacuum, and found that changing the wall by that amount produced changes in the discharge current; that is, this grid action effect was much smaller than the pressure change effect.

Mr. Davis: Thank you, Doctor. That is all.

(Witness excused.)

IRVING LANGMUIR.

Irving Langmuir was called as a witness on behalf of the defendant in sur-rebuttal, and having been previously sworn, testifies as follows:

The Court: He is made your witness for the purpose of sur-rebuttal then?

Mr. Haight: Yes.

Direct Examination.

By **Mr. Haight:**

Q. 1. Dr. Langmuir, I show you what purports to be a certified copy of a petition to the Commissioner of Patents, purporting to have been signed by you, and the accompanying specification and claims and drawings, which eventuated in a patent to you known as No. 1,558,437, and ask you if you recognize your signature to these papers?

Mr. Davis: May I ask, if your Honor please, to reserve objection until we see whether it is sur-rebuttal?

A. I recognize my signature to these papers which you have put before me.

Mr. Haight: I have not offered them.

Mr. Davis: I reserve objection until I know what it is.

The Witness: I recognize my signature to these papers which you have just shown me.

Mr. Haight: I offer the petition, specification, claims and oath and drawing in evidence, the same being dated October 27, 1913.

Mr. Davis: I object if your Honor please. I have not been shown it is sur-rebuttal.

The Court: To meet what, Judge Haight?

Mr. Haight: The purpose of it will be shown in just a moment.

Mr. Davis: I reserve my objection.

By Mr. Haight:

Q. 2. And Mr. Davis was your attorney in the prosecution of that application, was he not; it seems, to have been signed by him?

A. Yes.

Mr. Haight: This standing alone, of course, shows nothing; but I offer also in evidence a certified copy of a communication to the Commissioner of Patents, signed by Mr. Davis as attorney for Dr. Langmuir and dated November 27, 1915. The purpose of the two papers is this: Your Honor will recall that while Mr. Colpitts was on the stand there was exhibited to him a patent which had been granted to him and the claims in which referred to an "ionized stream," I think that was the expression that was used. The patent was one of those patents that was in the Interference record. The purpose of this offer is to show that Dr. Langmuir in an application for a patent for a device, which he states "consists essentially of an electron emitting cathode and one or more anodes thoroughly freed from gas, located in an envelop evacuated to such a high degree that an electron discharge can take place . . . without causing appreciable gas ionization by collision with residual gas molecules."

The purpose is to show that on November 27, 1915, he asked the Commissioner of Patents to declare an Interference between this application and the Colpitts patent to which I have referred, and copied into his application the claims of the Colpitts patent.

The Court: Then the Colpitts patent was put in evidence by the plaintiff?

Mr. Haight: Yes, sir.

The Court: And this is to meet the Colpitts patent?

Mr. Haight: To meet any inference that may be drawn by the plaintiff from the Colpitts patent.

The Court: In so far as this would serve that purpose?

Mr. Haight: Yes, sir.

Mr. Davis: I object to this on its face as immaterial, for this reason, and if necessary, I will call a witness to prove the practice of the Patent Office in that respect, but I do not think it is necessary. It seems to me it is apparent on its face. A man is issued a patent in this case, Mr. Colpitts, containing claims in a certain form, the form may be very bad and objectionable, but there they are. The only way in which an Interference can be had with a patent containing that claim, so far as that claim is concerned, is by copying the claim.

The Court: Does not that go to the weight?

Mr. Davis: I think not; I think it goes to the materiality. I suggest that for your Honor's consideration, it is a perfectly automatic thing. Here is a man who gets a patent, and I do not care what language he uses, if you want the Interference you must copy the claim in those words and every comma must be there, and any suggestion of the General Electric or Dr. Langmuir that they were doing anything by copying the language of these Colpitts claims is perfectly ridiculous, and nobody would think otherwise. If, for instance, he knew the Patent Office practice, and I am prepared to call an expert on the Patent Office practice, if necessary.

The Court: I will hear you, Judge Haight.

Mr. Haight: Mr. Ballard tells me that Mr. Davis is possibly in error in his idea of the Patent Office practice, but I do not think that makes any difference. The point is that in a patent or an application for a patent——

The Court: I have your point, and I think Mr. Davis' objection goes probably to weight, and whether it reduces the weight to approximately zero or not, is a question that is not determinable now. I think this is admissible, but what weight should be given to it, is another matter, assuming the Patent Office practice to be as stated by Mr. Davis.

Mr. Haight: All right, sir.

(The petition and specification and drawings were received in evidence and marked "Defendant's Exhibit No. 300." *See Volume VI, Defendant's Exhibits, page 1207.*)

(The certified copy of the communication was received in evidence and marked "Defendant's Exhibit No. 301." *See Volume VI, Defendant's Exhibits, page 1228.*)

Mr. Haight: That is all.

Mr. Davis: I think I would like to ask one question in re-direct examination.

By Mr. Davis:

Q. 3. Did you know anything about this letter to the Patent Office in which Mr. Colpitts' claims were copied at the time at which it was written?

A. I have no present recollection of the matter at all.

Mr. Davis: Thank you.

Mr. Richmond: Just a moment, please.

By Mr. Haight:

Q. 4. Do you recall, Doctor, whether or not you executed and swore to a preliminary statement?

A. I have no recollection at all concerning the procedure in connection with this patent.

Mr. Haight: That is all.

(Witness excused.)

(Whereupon at 5.30 P. M. adjournment was taken until Thursday, 11th November, 1926, at 10 o'clock A. M.)

GEORGE E. FOLK.

George E. Folk, was called as a witness in surrebuttal on behalf of the defendants, having been duly sworn, testified as follows:

Direct Examination.

By Mr. Haight:

Q. 1. Mr. Folk, you are the general patent attorney of the American Telephone & Telegraph Company?

A. I am.

Q. 2. You have been connected with the Patent Department of the Telephone Company for how many years?

A. Since 1915.

Q. 3. I show you a letter purporting to have been written by Charles Neave to H. B. Thayer on October 10, 1913, and ask you if you got that from the files of the American Telephone & Telegraph Company?

A. I did.

Q. 4. Who was Mr. Thayer?

A. Mr. Thayer in 1913 was president of the Western Electric Company, if I remember correctly.

Q. 5. And Mr. Neave?

A. Mr. Neave was the patent attorney at that time and did patent work for the Telephone Company and for the Western Electric Company.

Mr. Haight: I offer this letter and the accompanying report in evidence, the purpose of it being to show that at the date of the letter Mr. Neave advised the Telephone Company that Mr. Hewitt was then claiming that the audion came within his patents. Of course, the purpose of this is to show the reason why the Telephone Company exercised the option that the Hewitt agreement gave them——

The Court: One of the reasons for the license.

Mr. Haight: Yes.

Mr. Davis: The only point occurs to me is whether that is in rebuttal of anything.

Mr. Haight: You put in the Hewitt contract.

Mr. Davis: We put that in at our last session?

Mr. Haight: Yes, sir.

Mr. Davis: Then I have no objection.

Mr. Haight: This is the original, and if counsel are agreeable I will have a photostatic copy made and put in the record and have that marked and let them have a copy.

Mr. Davis: I have no objection to the letter.

(Received in evidence and marked "Defendant's Exhibit No. 324." *See Volume VI, Defendant's Exhibits, page 1349.)*

By Mr. Haight:

Q. 6. Do you know whether suit was brought by Hewitt on the agreement with the Telephone Company entered into with him?

A. There was.

Q. 7. And it was a suit for royalties which he claimed to be due from the Telephone Company by virtue of that agreement on account of the Telephone Company's use of the audion?

A. That is right.

Q. 8. And he was defeated in that suit?

A. That is correct.

Q. 9. It appears in the evidence that sometime in the early part of April, 1915, the Telephone officials or some of them at least learned that Dr. Langmuir had filed an application for a patent of the high vacuum audion. And it also appears that it was because of the filing of that patent that the Telephone Company determined to file an application for a patent on the same thing on behalf of Dr. Arnold, and also it appears that Arnold's application was not filed until November, 1915. Can you tell us the reason for the delay in the filing of the Arnold application between the time in April that I have referred to and the time that it was actually filed in November?

A. Perhaps I can do that best by telling the circumstances.

Q. 10. All right.

A. In the latter part of April, 1915, I received a letter from Mr. Thomas D. Lockwood, the general patent attorney of the American Telephone & Telegraph Company stating that a number of important questions had come up concerning the audion and asking me if I could not come on from Chicago where I was then practicing law, and help them out in the solution of the questions that had arisen.

He said the matter was very urgent and asked me if I would not telegraph when I could come. I telegraphed that I would be in New York on May 5th. I was there and met Mr. Lockwood and he explained the situation to me and stated a number of matters in which it was necessary to determine what should be done. One of them was the particular matter that you have referred to, that is the question of the high vacuum audion.

I immediately began investigation in these matters and found that there was so much involved that I advised them that I could not see that there was any particular hurry in filing that application in view of the facts as I understood them and suggested that they had better get someone to take charge of these matters and look into them thoroughly and he could devote his whole time to it.

The upshot of the whole thing was I was asked whether I would not enter the employ of the company and do that thing myself. They made me a proposition on Wednesday, the latter part of May, and I accepted it the next day, and telegraphed my wife that I was coming to New York and be ready to leave the following Monday and I went back to Chicago and was in New York again on the first of June, that is, within a week after the offer had been made to me I was on the job and I had several assistants looking up this matter and a number of others and I came to the conclusion that there was no special hurry about filing the application because we had never abandoned the invention and the only reason that I could see for rushing—I could see no reason for rushing it in the office because I could not see that there had been any statutory prior use of the invention, and there was no concern about it and I was very anxious to take the right step and I felt it was very important that we look into the matter and ascertain just what the facts were, what our company had done and what the prior art was so that I could discover whether there was an invention and if so what it was.

Within four or five months after I came to the company I had determined what should be done and had an application filed.

Meanwhile I had given a very careful consideration of a number of other matters which I considered were more urgent than that.

Q. 11. Will you mention some of these?

A. I made a memorandum of those that occurred to me and I checked them up to see that they did occur during that interval. One of the matters which I took up even before I came to the company on the first of June, that is, during that interval in May, was the Hewitt situation. Hewitt at that time was claiming royalties and it was up to us to determine whether royalties were due him or not and I remember I went into the whole situation very thoroughly during that summer, that was something that had to be taken up at once. If royalties were due to him he should be paid and if not we should tell him that. Within a year he brought suit against the company.

Another thing that was very urgent was the De-Forest-Marconi suit to which some reference has been made in this case. At that time there was a suit pending between the DeForest Company and the Marconi Company. The DeForest Company being sued on the Fleming valve patent and the Marconi Company, I believe, being sued on one of the DeForest patents. We were licensees under the DeForest and our interests were involved. Mr. DeForest was infringing the Fleming valve patent, and what about the Telephone Company, and it was very urgent to determine what we should do and so we looked into that situation.

I finally determined that we could do nothing but let the matter alone, but I did go into it very thoroughly.

Another matter that came up during that summer of 1915, was the Grisinger situation. We were using a repeater circuit that Grisinger claimed. We knew what it was and while there was an interference there were still some claims that bothered us. Finally, within a year after considerable negotiations we settled the matter with Grisinger by paying him a very large sum of money for the rights under his patent.

Another matter that engaged my attention during the summer of 1915 was the oscillating audion situation. I found that our company was developing a carrier current system that involved the feedback oscillating audion, and we did not have any patent application covering that broadly, and we were aware of the fact that there were other pending applications on the matter and I was looking into that to see whom that invention belonged to and what to do about it. I believe that matter is still unsettled.

That gives you some idea of the work I had to do that summer. In addition to the oscillating audion situation we had the whole carrier current patent situation before us and to find out just what patents we might need in order to be free of infringement and I looked that up carefully.

Then another matter that was very urgent and I believe was really the first thing that I did was to file a patent application on a wave filament. We had had an application pending for a number of years on what we considered a very important invention, but it had been finally rejected and abandoned in the Patent Office. There had been publications of this, the time to refile was short and that matter was so urgent that I personally prepared this application and had it filed on July 15, 1915.

The original application did not give the mathematical equations involved and I found considerable difficulty in presenting that because it was a purely mathematical equation, in such a way to have the Patent Office understand it. This we consider one of the most important patents we have taken out in a number of years. That gives you some idea of a few of the things that engaged my attention that summer, and I think you will appreciate that the responsibility of those things turned over on me, was great.

Q. 12. I take it then that you had a very busy summer?

A. Very busy summer.

Q. 13. And you took up this Arnold situation and filed it as soon as you could reasonably get to it?

A. As soon as I could get the information and data that enabled me to do what I considered best.

Q. 14. There has been offered in evidence the file wrapper of a patent No. 1,297,309, issued to Dr. Arnold on or about March 18, 1919, Plaintiff's Exhibit 170. Do the files of the Western Electric Company show how the subject matter of this patent or the question of applying for a patent covering the subject matter of the patent was brought up?

A. They do.

Q. 15. I show you what purports to be a letter written by Mr. Scribner to Mr. Tanner under date of February 10, 1915, enclosing a memorandum from H. D. Arnold, dated February 8, 1915, and ask you if those are papers in your file which show how these matters were brought out?

A. These papers are on file with the Western Electric Company.

Q. 16. And who is Mr. Scribner?

A. He was the chief engineer of the Western Electric Company in 1915.

Q. 17. And who is Mr. Tanner?

A. He was the general patent attorney for the Western Electric Company.

Q. 18. And who is H. D. Arnold?

A. H. D. Arnold is the Arnold who had filed an application for a high vacuum tube in interference with the Langmuir application.

Mr. Haight: I offer this letter of Mr. Scribner's and the enclosed report of Dr. Arnold in evidence, for the purpose of showing how the idea of applying for a patent, the patent in question, initiated and I am going to ask for consent of counsel that photostat copies be put in rather than the original.

Mr. Davis: I have no objection and will consent to the substitution.

(Received in evidence and marked "Defendant's Exhibit No. 325." *See Volume VI, Defendant's Exhibits, page 1358.*)

By Mr. Haight:

Q. 18a. Now, Mr. Folk, it appears that in the prosecution of this patent application the office rejected certain of the claims upon certain patents which had been issued to Dr. Coolidge and it also appears that no effort was made to take the Arnold invention back of the Coolidge filing dates, but that the claims of the Arnold application were amended so as to avoid the Coolidge references. Did you have charge of the prosecution of this application and do you know the circumstances and reason why no effort was made to take the Arnold invention back to Coolidge?

A. I had general responsibility for the prosecution of that application and I do know the reason why the action that was taken was taken.

Q. 19. Without asking you to quote from the correspondence on file I will ask you to look at the file if you need it to refresh your recollection and just state the circumstances and I will make the file available to the other side.

A. After the Arnold application had been filed for about a year, my attention was called to the fact that a Coolidge patent had been issued containing claims which might be made in the Arnold application. That means that although the two cases had been pending contemporaneously in the Patent Office, the Patent Office had inadvertently issued a patent to Coolidge without declaring an interference as should have been done.

The question was up to us as to what we should do and I had a report made on the patent in order that I might get the facts to enable me to reach a conclusion as to just what we should do.

I find a report in my files as dated December 8, 1916, signed by P. I. Wold that discussed the various claims of the Coolidge patent, stating that these claims describe substantially what Arnold had done broadly and that the broadest of the claims, Claims 25 to 28, might be made in the Arnold application, but that in view of the prior art mentioned in this report in the writer's opinion the claims were not patentable and the interference should not be sought for something which he considered was unpatentable.

I reached that conclusion myself after investigating it and determined that we should simply ignore that patent instead of asking for an interference on a claim which in our view was clearly unpatentable.

In other words, although we were convinced that we could antedate the filing date of Coolidge without any difficulty, that it would be unnecessary and unwise to do that in view of the situation as thus stated.

Q. 20. Just to make that clear, in view of the fact that the Coolidge patent had issued and an interference had not been declared, what would have been the effect so far as you are concerned, if you had gone into interference with the Coolidge patent and had prevailed?

A. We would be getting the patent for claims that we did not consider should be allowed to anybody.

Q. 21. If you had gotten that patent?

A. Then we would, if we wanted to, we might have brought suit under 4918 for the cancellation of the Coolidge patent, but I did not consider the matter of sufficient importance to waste our time and energy in fighting something that we decided we should ignore.

THE COURT: What was the Coolidge patent for?

MR. HAIGHT: It was this bombardment.

MR. RICHMOND: It was the Coolidge X-ray tube.

THE WITNESS: It was the Coolidge Patent No. 1,120,349 of October 31, 1916.

MR. HAIGHT: There were three of them mentioned—cited, but one of them is the Coolidge X-ray patent.

MR. DAVIS: There were some claims of clean-up in the Coolidge X-ray tube patent.

A. (Continued.) My attention was next called to this matter some time later by a letter from Mr. Tanner the general patent attorney of the Western Electric Company, asking for my advice as to what should be done after the Coolidge patent had been cited for a reference. This was some two years after the original investigation. Mr. Tanner says: "Attached is a copy of a memorandum from Mr. Beatty," and asking for my advice as to what we should do under the circumstances.

By MR. HAIGHT:

Q. 22. Who was Mr. Beatty?

A. He was the young man who had the actual charge of the prosecution of the Arnold application.

Q. 23. In the Patent Department of the Western Electric Company?

A. Yes. Mr. Tanner undoubtedly sent that to me on this date because in Mr. Beatty's memorandum was a statement that he was informed by one of my assistants, Mr. Rose, that the question of the interference between the Arnold application and the Coolidge patent had already been given consideration by me and I wrote to Mr. Tanner telling him that that was a fact and since the claim seemed to be unpatentable, advising that we not make them, but that we cancel all the claims except those that we consider as clearly patentable over the prior art, not merely the Coolidge patent, but the prior art in general.

Q. 24. Then am I correct in understanding that the reason why no effort was made after the Coolidge patents were cited against the Arnold applications, to take the Arnold date of invention back of the Coolidge filing date, was because you considered that the claims of the Coolidge patent, which conflicted with the Arnold claims were unpatentable?

A. Yes, absolutely. The records bear that out.

Mr. Haight: You may cross-examine.

Mr. Davis: I understand that if plaintiff desires any of these papers this file will be offered.

Mr. Haight: Yes.

Mr. Davis: And that I may postpone that decision until I have a chance to look them over.

Mr. Haight: Yes.

Cross-Examination.

By Mr. Davis:

XQ. 25. You spoke, Mr. Folk, of a suit which Dr. Hewitt brought against the telephone company to collect royalties which he claimed were due him under the license agreement?

A. Yes.

XQ. 26. The articles which you had made with respect to which that claim was made by Dr. Hewitt, were these three-electrode repeater tubes which you used in your telephone circuits?

A. That is correct.

XQ. 27. And those were the tubes of the type described in the Arnold application which was involved in the interference with Dr. Langmuir?

A. That is correct.

XQ. 28. And that suit was Hewitt against the American Telephone & Telegraph Company, Judge Mayer's decision, in 272 Federal Reporter, 1914?

A. That is correct.

XQ. 29. The Court of Appeals decision is in the same volume at page 392. It was written by Judge Hough?

A. Yes.

XQ. 30. The situation in this suit was that the only question which could be debated was the question of infringement, was it not?

A. It was hardly the question of infringement.

XQ. 31. The question was whether the claims of the Hewitt patent properly construed covered the device which you used?

A. That is correct.

XQ. 32. You had admitted the validity of the patent substantially by taking the license?

A. We never denied the validity of it. We questioned whether it covered the high vacuum device.

XQ. 33. And the Hewitt device was a mercury device?

A. That is correct.

XQ. 34. And therefore a device operating at relatively high gas pressures?

A. Yes, except that Hewitt was contending at that time and had contended at that time his invention was based on and covered a high vacuum or low vacuum or any kind of vacuum, any means of getting electrons from the cathode to the anode.

By Mr. Davis:

XQ. 35. And that was the real contention of the suit, was it not?

A. That was practically the contention.

XQ. 36. And you defended that suit on the ground that these devices which you are saying operated on entirely different principles to Dr. Hewitt's device?

A. That was correct.

XQ. 37. Because your devices had a very high vacuum, and were independent of the presence of gas in the tube?

A. That is correct.

XQ. 38. Do you remember the summary which Judge Mayer made of the contentions from the brief of Defendant's counsel which he accepted, on page 199 of the Federal Reporter (handing book)?

A. I find that there is such a summary.

XQ. 39-40. Judge Mayer says:

> "On the point that this minute amount of gas does not take any part in the operation of defendant's devices, I accept the summary of facts in the brief of defendant's counsel.
>
> "(1) The pressure does not rise when the device is heated as it would if an appreciable amount of gas were present.
>
> "(2) No appreciable amount of current flows between filament and grid and such current would flow if gas or vapor took any part in the operation of the device. There is a small leakage current there, amounting between filament and plate, but it is ineffective for any purpose and does not figure in the operation.
>
> "(3) The device works no differently, if even less gas or vapor is present; it is merely useless and uneconomical to reduce the pressure to a lower point.

"(4) The space inside of the defendant's tubes does not glow, as it would if gas were taking part in the operation.

"(5) During operation, the temperature of defendant's filament does not change as it would if appreciable gas were present.

"(6) If, during operation, the temperature of the filament is intentionally increased, the current blow between filament and plate is not altered as it would be if gas took part in the operation of the device.

"(7) If gas or mercury is introduced into the defendant's tube while the device is operating, the usefulness of the tube is ended, as its amplifying qualities were destroyed."

Was that a substantially correct summary of the position taken by your company in that suit?

A. I do not recall; I dare say it is. I know I never questioned that summary.

XQ. 41. You did not question the summary?

A. No, I do not question that summary. I do not pose as an expert on that subject matter; I simply accepted that Court's view of the testimony.

XQ. 42. And you were in touch with the suit, of course?

A. I was.

XQ. 43. Do you remember that when this so-called Langmuir Interference was argued before the Examiner of Interferences in the Patent Office, that you took part?

A. On the question of priority, yes.

XQ. 44. And at the beginning of your argument, near the beginning of your argument, you very frankly stated that you were going a little outside of the record and then proceeded to say something about these matters, about which you have testified this morning. I will read from the record as I have it here.

MR. HAIGHT: I would rather you show it to him.

XQ. 44a. Have you any doubt that this is the record of the argument, Mr. Folk?

A. I remember something of that kind. I dare say that is a correct report of what I said.

XQ. 45. Then you said, did you not——

MR. HAIGHT: What is that?

XQ. 46. You said, did you not, in that argument: "When the Telephone Company in April, 1913, heard of this claim of the General Electric Company"——

THE WITNESS: 1913?

XQ. 47. "1915." I beg your pardon.

> "When the Telephone Company in April, 1915, heard of this claim of the General Electric Company, claiming that it made a higher vacuum tube, the record refers to the fact that the company realized that they had that tube in commercial operation in the trans-continental lines, and in other commercial circuits, it never occurred to them that this was not their development work, and when they understood the General Electric Company was claiming that which might be work resulting from their laboratory work, they naturally became excited.
>
> "I was practicing law in Chicago at that time and got a very urgent telegram to come to New York. That was responsible for my giving up my business in Chicago, and I never worked so hard in my life as I did to get this application filed, and I filed it as quickly as I could."

Is that a correct report?

A. It is substantially correct. I find the telegram was the other way. The request was that I myself telegraph, and I did so. What I got was a letter, was a request, that I should send a telegram.

MR. DAVIS: That closes the cross-examination subject to these papers we have not had time to locate.

RE-DIRECT EXAMINATION.

By MR. HAIGHT:

RDQ. 48. At the time you were arguing this matter in the Patent Office, did you make a thorough examination of your records and files, and whatnot, as you did preparatory to testifying here?

A. I did not. I did not expect to say a word only I possibly felt that some unfair things had been said about Dr. Arnold and in the heat of the moment, I got up and made that reply.

RDQ. 49. I presume there was firmly fixed in your mind the idea of working very hard in New York in the hot summer months, and you did not attempt to differentiate whether you worked on Hewitt against the Telephone Company or Arnold vs. Langmuir?

A. I was working on all of them. I might say I was keeping them all going.

MR. HAIGHT: That is all. Now, Dr. Arnold.

HAROLD D. ARNOLD.

HAROLD D. ARNOLD, was recalled as a witness on behalf of the defendants:

DIRECT EXAMINATION.

By MR. HAIGHT:

Q. 1. Doctor, referring to your notebook about which you were cross-examined, I notice that from June 3, 1912, to October 2d, and including October 28, 1912, there were only seven entries, and those entries covered pages 134 to 136; is that correct?

A. That is correct.

Q. 2. Will you just give us the dates of the various entries in that period of time?

A. The dates are June 3d, June 6th, August 15th, August 23d, August 24th, August 26th, October 28th.

Q. 3. Now then, am I correct in stating that from October 28th, 1912, on to January 2d, 1917, nearly five years, there were in that book only ten entries?

A. I count eleven, but perhaps I am mistaken in my count. Just a moment. Unless I am mistaken in my count, there are twelve entries, but perhaps I had better give the dates; then it will appear how many there are.

Q. 4. Please give the dates.

A. December 23, 1912; February 3, 1913; May 1, 1913; November 29, 1913; March 4, 1914; March 7, 1914; May 21, 1915; September 1, 1915; September 2, 1915; November 1, 1915; December 7, 1915; January 2, 1917.

Q. 5. You are right; there are twelve. I had left out two that I apparently had lost. Now, those entries cover from pages 137 to 148 inclusive; is that right?

A. That is correct.

Q. 6. I notice that one of these entries, that of December 7, 1915, reads as follows: "Whole month has been consumed in planning winter's work and in fussing about patents." Is that correct?

A. That is correct.

Q. 7. I notice that some of the other pages refer to various scientific formulæ, and other drawings upon them; is that correct?

A. That is correct.

Q. 8. Now, you did not seem to be very regular in the entries that you made in this book from June of 1912, and the subjects which you selected for entry were not governed by any particular standard, is that correct?

A. That is correct.

Q. 9. Will you please tell us what your method was of making entries in the notebook; I mean by that, what kind of entries did you make; did you have any fixed plan, or what?

A. No. There is no plan of entries used in our keeping of notebooks in our laboratory. The books are furnished to the members of the laboratory, in order, if possible, to avoid their using loose sheets of paper for taking data, which loose sheets of paper might be lost; but there is no requirement whatever as to how entries shall be made, or when entries shall be made, or what type of entries shall be made; that is, it is entirely at the discretion of the person who is using the book, and in many cases—and I think this is rather common practice—whenever I personally took the observations of instruments, and had my own book handy, I would write those down. That relates to the early part of my work when I was working in direct experimentation; but aside from that, there was no regularity whatever in my method of keeping my book.

Q. 10. I notice that before August, 1912, there seems to be entered in the book a great many readings and things of that kind; is that so, and that after that time there were very few, if any?

A. Yes, sir. My book up until October 28, 1912, and that comprises 136 pages, out of the 148 that have records on them—was devoted almost exclusively to the record of my own observations in connection with the mercury arc work, or other minor problems I might be engaged upon. As I have already testified, I think, on October 28th, or between October 28 and November first, the type of my employment changed in this respect; that whereas I had been working with the mercury arc at the laboratory bench, and making observations myself prior to November first, that on November first my duties were broadened by the addition of other problems, specifically the problem of the development of the high vacuum audion, and by the addition of other employees; so that from that time on, I personally did very little work at the laboratory bench myself, and that was largely, I presume, the reason that from then on, there were so very few entries in my book.

Q. 11. Now, I do not know whether you testified as to exactly what Mr. Nicolson's duties were or not. If you did not, will you please state them in a general way?

A. Mr. Nicolson, who came with us in November, 1912, had assigned to him the general problem of developing the process of making Wehnelt oxide filaments. His work on that subject was interrupted by the necessity of his taking observations on the Von Lieben-Reisz-Strauss repeater during the early part of 1913, but from then on during the year 1913, his orders were to do the best he could to develop the process of the manufacture of the Wehnelt oxide filaments, and that was the only problem that was assigned to him during the year 1913 and 1914.

Q. 12. Did you direct the details of his work in that respect?

A. Not at all.

Q. 13. Did you acquaint yourself with the details of his work?

A. From time to time. Mr. Nicolson would tell me of interesting things that he had discovered. Occasionally he would ask me to go into his laboratory room to see things that he thought might interest me, and from time to time I would drop into the room, quite uninvited, in the course of inspection of the laboratory.

Q. 14. Did you instruct him to interest himself in the construction of audions other than the filaments; did you instruct him to study the methods of pumping audions, or preparing them to hold their vacuum?

A. No. That was quite out of his field. If he did any such work, it was entirely on his own volition.

Q. 15. Now, referring to the entries and notebooks of those working under you, were those entries brought to your attention with any regularity or in accordance with any settled system or practice?

A. Not at all. It is very rare indeed for a supervisor to see any entries in an employee's notebook. The book is kept entirely for the employee's own personal convenience.

Q. 16. Dr. Arnold, Dr. Langmuir has testified in this case in reference to a conversation that he had with you at a meeting of the Physical Society, held at Columbia University on October 13th, and has recited that conversation as follows:

> "A. There was considerable discussion after the meeting, mostly by Dr. Arnold. He pointed out to me——"

THE COURT: On what?

MR. HAIGHT: On the record, page 1235.

THE COURT: I am wondering whether you could give the number of the question, so that it can be identified in the printed record as well.

MR. HAIGHT: In answer to Q. No. 198.

Q. 17. I will now read it:

> "A. There was considerable discussion after the meeting, mostly by Dr. Arnold. He pointed out to me that the 3/2 power law had been previously published by Child in 1911, and that was for the case of parallel plane electrodes. In my paper I had also given the derivation of electrodes in the form of a wire as the center in the axis of a cylinder. Dr. Arnold also stated that he felt that it was very doubtful if I had really obtained currents of such voltages as I had spoken of, 250 volts, that were free from blue glow and ioniza-

> tion effects. After the meeting, I had a longer talk with Dr. Arnold, and he told me that they had been working on electric discharges in evacuated tubes from hot cathodes and had used the Wehnelt cathode, and said that they were particularly interested in low voltages, much lower voltages than those I had been talking about. I think that he spoke of voltages of 20 to 30 volts as being the voltages that he intended to use in operation."

Does his recital of that conversation correspond with your recollection of it?

A. No. A part of his recollection corresponds with mine but a part of it is quite different.

Q. 18. Please state the part that corresponds with your recollection and state wherein your recollection differs from his?

A. I remember distinctly speaking after Dr. Langmuir had completed his talk, as is customarily done in the meetings of the American Physical Society, by those who desire to comment upon the speaker's words, and in my comments I said that Lilienfeld had obtained the 3/2 power law experimentally and that Child had derived the 3/2 power law mathematically and also remarked that I had worked it out myself prior to the time I had found Child's work. To that extent my recollection is I think in line with Dr. Langmuir's recollection of the matter.

The difference between our recollections as to what I said immediately after the completion of his talk is as to my doubt of his having obtained a discharge free of blue haze at 250 volts. I remember quite well what I intended to say, although, of course, I cannot remember the words that I used and what I intended to say, and what I think I did convey was this, that if one is looking for blue haze in a tube that is brilliantly lighted with a tungsten filament, then he is apt to be misled by the brilliance of the filament into thinking there is no blue haze when there may be blue haze; that this had been very distinctly brought home to me in my work where I had been using Wehnelt oxide filaments which are very dull and so did not conceal the blue haze much and even with those I had found that if I covered my head and the tube with a black cloth, as a photographer does when he is preparing to take a picture, that then blue haze would sometimes become apparent, that had not been apparent in open daylight.

I had intended to offer a word of warning to those who might be experimenting with brightly lighted tungsten filament, but I did not doubt at that time or had no reason to doubt that Dr. Langmuir had gotten discharges at 250 volts free of blue haze.

Even if I had doubted it I think I should not have mentioned it in my comments on his paper, but I certainly did not doubt it because I myself had had such discharges in the laboratory during the preceding months and was quite familiar with the discharges up to 200 volts or more in which there was no blue haze present even if the utmost precautions were taken to see it.

So on that point I think that Dr. Langmuir has either not remembered what I said at the time or had placed a construction upon it that was quite foreign to what I had in mind.

Q. 19. Did you tell him that you and the Telephone Company had intended to use twenty and thirty volts in operation?

A. No, I could not have told him that. After the formal part of the meeting was over, Dr. Langmuir came to me and asked for the reference to Child's paper and we had a few moments' conversation. I cannot recall what we talked about at that time now, but I could not have told him that we were planning to use voltages of the order of twenty or thirty volts on the plate circuit for vacuum tubes.

Q. 20. Why?

A. Because at that time our plans were all made for using higher voltages than that. We were using higher voltages than that and we were starting to engineer our equipment on the basis of 120 volts on the plate circuit, that being one of the voltages available in the telephone plant.

Whatever misunderstanding there is about this may possibly have arisen from the fact that we were using, as we now are, too, the twenty-four volts storage battery service of the telephone office for the filament current in our vacuum tubes and I can think of no other way in which such a voltage as twenty-four or twenty to thirty volts could have been mentioned except in that connection.

Q. 21. There has been a lot of talk in this case about blue haze and it has occurred to us that it might be interesting to his Honor to see blue haze in a tube and to point out the difference between the visibility of blue haze in a tube employing a tungsten filament and one employing a Wehnelt oxide filament. Are you prepared to demonstrate blue haze and the differences of which I have spoken?

A. I have a tube prepared for that purpose and if we have no misfortune in making the demonstration, I think that can be done very quickly.

Mr. Haight: Would your Honor like to see it?

The Court: How long does it take?

The Witness: About five minutes.

The Court: If it can be demonstrated in five minutes then we can do it now or at two o'clock, because I have an engagement. Suppose you do it at two o'clock.

AFTER RECESS.

MR. HAIGHT: Dr. Arnold is going to make the demonstration for the Court.

By **MR. HAIGHT:**

Q. 22. The last question was with respect to the demonstration and you stated you were prepared to make it. Will you please do so?

A. The tube is on the side table and I think we may go to the table.

THE COURT: All exhibits which have been offered and admitted but which have not actually been delivered to the clerk are to be delivered to him not later than the twenty-second day of the present month.

(Here the demonstration was made and the following took place.)

THE WITNESS: The tube which I have here is equipped with two filaments, one of them is a Wehnelt oxide filament of our standard type of the size that we use, set into the tubes, and the other filament is a tungsten filament of about 3/1000 of an inch diameter. The currents which are to be supplied to those filaments are those which would normally be used in operation giving the Wehnelt oxide filament a temperature of between a thousand and eleven hundred degrees K. and the tungsten filament has a temperature of about 2500 degrees K. This tungsten filament is of course operated as a tungsten filament and not as a thoriated tungsten filament. If it were operated as a thoriated tungsten filament, the temperature of operation would be somewhat lower.

The tube is also provided with a plate to which the electrons may be drawn and the tube is evacuated to a pressure of about eight microns of argon gas. Argon is used in order that the blue haze may not change its character too rapidly during the demonstration and is particularly good for this purpose because the color of the haze in argon is rather similar to that obtained in nitrogen which is the normal residue of an exhaust from air.

Now, we will apply to the Wehnelt oxide filament its normal current and the tube is so arranged that the wires can be rather easily short-circuited so that we better not touch the tube very much. This gives an idea of the brightness to which the Wehnelt oxide filament is normally operated. In fact, this is somewhat brighter than the filament that we use in the telephone plant at present.

Now, we will apply between the negative terminal of this filament and the plate a voltage of about sixty-six volts and the tube shows blue haze of a color that is quite customarily seen in exhaust process and of a magnitude that is quite customarily seen.

I want to make quite clear that it is much easier to see blue haze under these conditions than it is with a bright tungsten filament.

We will now light the tungsten filament with its normal current and it is better not to look too fixedly at the filament.

By The Court:

Q. 23. There is no blue haze there now?

A. No blue haze at present. The filament is lighted. We will now apply to the plate the same voltage that we had in the previous case and there is blue haze in the tube. It will be difficult to see it. In fact you would have to very carefully shield your eyes and look past the edges of the plate to see it. We can make it more apparent by increasing the temperature of the filament slightly which will increase the electron emission and thereby increase the blue haze.

Can you touch the connection on and off and see if we cannot discover a little flash of blue haze in there?

Q. 24. Is there as much blue haze in there now, in fact, as there was with your other filament?

A. Very approximately the same under these conditions. It probably is a little less but not very much less. I am told that the change in plate current caused by the blue haze in our laboratory test were in the ratio of four to three, so that would be roughly the ratio of the amount of ionization under those two conditions.

We can go back to the Wehnelt oxide filament and show that the condition of the tube has not appreciably changed. If the tube had been filled with nitrogen then a clean-up would have occurred during this test, but being filled with argon the clean-up is very much less because the argon is a very difficult gas to clean-up with this process.

I want to correct my previous statement about the results in the laboratory. The fact is that the ratio of the current to the plate was four to three, four being from the Wehnelt oxide and three from the tungsten filament. So it is not fair to deduce that the ratio of the blue haze would be exactly in that same ratio.

The Court: Are there any questions which the other side may bring out by cross-examination while the experiment is going on?

The Witness: Now, we see that the blue haze is again visible with the Wehnelt oxide filament lighted and in order that we may be quite sure of our test, without disturbing the connection of the B-battery to the plate, we will change the filament connection so that we light the other filament in order that we may be quite sure that the plate is at the same potential in both experiments.

THE COURT: Judge Haight, you were examining Dr. Arnold.

MR. HAIGHT: I am finished.

THE COURT: Mr. Davis, do you wish to cross-examine with respect to the experiment, while we are here?

CROSS-EXAMINATION.

By MR. DAVIS:

XQ. 25. What was the current in the plate?

A. We have no meter in the plate circuit at present and perhaps I can find out what the value was in the laboratory. I am told that with sixty-six volts on the plate in the laboratory, which is approximately the voltage that we have here now, the current to the plate with the Wehnelt oxide filament was about twenty milliamperes and with the tungsten filament was about fifteen milliamperes.

XQ. 26. Have you the diameter of the tungsten filament?

A. It is approximately 3 mil. wire.

XQ. 27. And the current in the filament?

A. The current in the filament was 1.14 amperes. There are two strands in this filament but the two strands are in parallel, one lead to the filament going to the top of the hairpin and the other lead going to both legs of the hairpin.

XQ. 28. So that you get 0.557?

A. 2.28 total amperes.

XQ. 29. And each of these three mil. filaments carries 1.14 amperes?

A. That is correct, and the power in the tungsten filament is thirteen watts.

XQ. 30. And the drop in each separate tungsten filament?

A. 5.7 volts.

XQ. 31. Can I have that information on the Wehnelt?

A. Yes, sir. On the Wehnelt oxide filament the current is about three amperes, the voltage is four volts and the power is twelve watts.

XQ. 32. That is a single filament?

A. That is a single filament. The reason for using the two legs of the tungsten filament in parallel in this experiment was simply for constructional purposes in order that we might get the same power dissipated in both filaments at about the same voltage applied and of course tungsten would be of much higher resistance than the Wehnelt oxide filament and we put the legs in parallel.

(The witness thereupon resumed the stand.)

By Mr. Davis:

XQ. 33. These figures you gave me, Doctor, were the figures on currents actually used in the room?

A. The currents from the filament as you saw the tube first were those that I have given you; but in order to emphasize the blue haze, and with the tungsten filament at the latter part of the experiment, we increased the current through the tungsten filament to a somewhat higher value.

XQ. 34. Now, did you say this morning, referring to Mr. Nicolson, that his orders were to make filaments?

A. That is correct.

XQ. 35. And that was all his orders were, to make, is that it?

A. That is correct.

XQ. 36. He was not supposed to make tubes?

A. Except as he might care to make them in testing under his own control the goodness or badness of the filaments he might make.

XQ. 37. If he did make any tubes, who exhausted them?

A. They were exhausted in our small glass working shop, either by Mr. Trimble or one of Mr. Trimble's assistants.

XQ. 38. So that really there was not much difference between a tube which Mr. Nicolson had exhausted, and any one else's tube, so far as the exhaust was concerned?

A. There might be a very great deal of difference, because as I think I have explained, with the great variety of Wehnelt coatings that Mr. Nicolson used, peculiar pump procedures were sometimes necessary to, in our slang terminology, "open-up" the emission of the filament.

XQ. 39. You were not opening up filaments in those days, were you?

A. Oh, yes. That procedure was found to be necessary with almost the first Wehnelt oxide filaments that we made, it was found necessary or desirable to operate them in the presence of blue haze for some little time.

XQ. 40. What was that for?

A. In order to get the electron emission from them started, it apparently makes a chemical change in the surface of the filament that was not understood at the time. As a matter of fact, I think it is not now very completely understood.

XQ. 41. Now, the object of this filament which Mr. Nicolson was making, of course, was to make tubes ultimately, rather than filaments, was it not?

A. That is correct.

XQ. 42. And you were desirous, were you not, of having filaments which would work in a tube?

A. That is correct.

XQ. 43. And would work in a good tube?

A. That is right.

XQ. 44. And of course the bombardment, if there is any bombardment, does change the emission of the Wehnelt filament, does it not? Suppose the cathode is heated by ion bombardment, does not that change the emission?

A. If the bombardment is sufficient to change the temperature, then the emission changes. I think that aside from that the bombardment produces comparatively little effect on the emission.

XQ. 45. The Wehnelt filament is rather more sensitive to temperature changes, is it not?

A. Well, I think it is not much more sensitive to temperature changes than any other filaments. All filaments obey the same general law of emission, but it happens that the Wehnelt oxide filament emits more electrons at a given temperature than the other filaments do. Perhaps I may say that the same number of degrees temperature change at the working temperature of the Wehnelt cathode, will change its emission more than that number of degrees change in temperature at the working temperature of a tungsten filament would change the emission in a tungsten filament.

XQ. 46. So that in order for Nicolson to know whether he was succeeding or not, it was necessary those filaments should be mounted in good tubes, and the tubes tested, was it not?

A. Well, the tubes had to be of a sort suitable for him to draw his conclusions from. The tubes need not have been tubes that would be satisfactory for any commercial use. It was understood particularly in the temperature emission characteristic of the filaments.

XQ. 47. Suppose one of his filaments was mounted in a tube that had a bad vacuum. Would you consider the data obtained from that tube would be very helpful to you in considering whether that was a good filament?

A. Yes, I think it would be very helpful indeed as indicating the emission from the filament, because you see the emission from the filament is just as readily measured in the presence of a poor vacuum as a good.

XQ. 48. Maybe just as readily measured, but it may not be the same, may it?

A. It would not be the same if the filament were very much affected by the presence of gas; it happens that the Wehnelt oxide is not very much affected by the presence of gas.

XQ. 49. You did not know as much in those days as you know now about these things?

A. No, sir; not nearly as much.

XQ. 50. And you were trying to develop, as I understand your testimony, a tube for use in this transcontinental circuit, among other things?

A. Yes, that was the general aim of our work.

XQ. 51. And is it at all probable that you would have let Nicholson, who was responsible for making the filaments, carry on his tests ordinarily under conditions which were different from the conditions from which the tube would be used in as important a matter as vacuum?

A. Oh, yes, indeed.

XQ. 52. Why would you have done that?

A. Because in the first place, Nicolson was his own master as to the nature of his tests.

XQ. 53. You were very close to his work, were you not?

A. I knew in a general way about the conduct of his work.

XQ. 54. Actually were you not very close to his work?

A. I think I can only explain that by stating again, as I did this morning that Nicolson called to my attention the parts of his work that he thought were very interesting to me, and that from time to time I dropped into his laboratory, either at his request or on my own volition, to see what was going on, but I presume, according to my present recollection, I was not familiar with 10 per cent. of the work that he did. That 10 per cent., however, was probably the most important part of the work that he did, at least he thought so.

XQ. 55. Please do not misunderstand me, I can appreciate that you may have deliberately put a filament in a bad vacuum, to see what it would do in a bad vacuum. That would be a perfectly legitimate test, and I am not setting a trap in connection with some use of that notebook in the slightest degree. I am simply asking you whether as a scientist and research engineer, knowing these tubes, or believing these tubes, as you say you did, were to be used on this transcontinental line, were to be used with a high vacuum, you would have had them tested as a general proposition in any other kind of a vacuum?

A. Yes, I think I ought to explain that thing quite fully in view of your question. There are two things to be carefully distinguished; one is the number of electrons that will come out from the filament, and the other is how a tube will behave in a high vacuum. The number of electrons that will come out from the filament, particularly in the case of the Wehnelt oxide filament, is not much influenced by the vacuum, so that a test in a poor vacuum is easy, quick and entirely indicative of the number of electrons that will come out, but the operation of a high vacuum tube as a repeater can not be thoroughly investigated, nor would the results from it be truly indicative, unless it were operated in a high vacuum, because its operation takes place in the presence of space charge, and does not depend upon the total number of electrons from the filament.

XQ. 56. That means, does it not, that you might let Nicolson make a rough test in a vacuum, an easily pumped vacuum, but before you had passed that filament, you would make him put it in a good vacuum?

A. Oh, no. No. These tests as to the filament, would be quite conclusive in a poor vacuum.

XQ. 57. Although changes in the vacuum would affect the saturation part of the curve, would it not?

A. Somewhat, but not very much, in the case of Wehnelt oxide filament, as a rule.

XQ. 58. Are you familiar with Dr. Van der Bijl's testimony on that subject in the Interference case?

Mr. Haight: I object.

Mr. Davis: I ask if he is familiar.

Mr. Haight: That does not make any difference.

The Court: I can not tell until the next question. It may be wrong, but I will overrule the objection to this question without prejudice to any objection that may be made to the next question.

The Witness: What is the question?

(XQ. 58 repeated.)

A. No. I have not seen that testimony for a good many years.

XQ. 59. You do not remember what he said about them?

A. I do not remember what he said.

XQ. 60. Now, I understood you to say, and correct me if I am wrong, that the only reason why Nicolson should ever make any tubes or have any tubes made, was to test those filaments; is that right?

A. Unless of his own volition he wanted to conduct experiments along inventive lines of his own.

XQ. 61. Do you remember the tube N-2, the adjustable audion?

A. I remember there was such a tube.

XQ. 62. What was the purpose of that experiment?

A. As I recall that tube, it had an adjustable element, moved by a magnet on the outside with which Nicolson was investigating how the current through the tube varied with the change in spacing.

XQ. 63. That was an experiment that you knew about at the time, was it not?

A. Yes, I knew about that at the time.

XQ. 64. That had nothing to do with filaments, had it?

A. Comparatively little to do with filaments, nor was it an experiment that I initiated.

XQ. 65. And all those N-tubes were Nicolson's tubes?

A. I can not answer as to that.

XQ. 66. This N-2 was Nicolson's tube, the one we have been talking about?

A. The N-2 tube was a tube designed by Nicolson.

XQ. 67. You do not remember whether the letter N stood for Nicolson?

A. Whether the letter N stood for Nicolson, and whether Nicolson designed all the tubes in the record which show a letter N, I do not know.

Mr. Davis: I think that is all, if your Honor please.

Mr. Haight: No re-direct.

(Witness excused.)

Mr. Richmond: I would like to offer a few exhibits and things that were marked for identification. I would like to offer Exhibit M for identification which is the abstract of Langmuir's talk before the Physical Society in October, 1913, as this abstract is printed in the official publication of the American Physical Society for November, 1913.

(Received in evidence and marked "Defendant's Exhibit No. 326." *See Volume VI, Defendant's Exhibits, page 1361.*)

Mr. Richmond: L for identification, which is a page of the Interference record with some points indicated by crosses on it that was produced by the witness——

Mr. Davis: It was shown to Dr. Langmuir during his cross-examination.

Mr. Richmond: Oh, yes, it was shown to Dr. Langmuir during his cross-examination. It is page 1176 of the Interference record.

The Court: Is this one of the exhibits?

Mr. Richmond: It is one of the exhibits modified. Some markings were superposed upon it.

The Court: I see.

(Received in evidence and marked "Defendant's Exhibit No. 327." *See Volume VI, Defendant's Exhibits, page 1363.*)

Mr. Richmond: In response to a request, I am not sure at the moment whether it was made in cross-examination or informally, but in response to a request from our opponents, I furnished to them and marked for identification N some data sheets about the nitrogen filled tube and also on the helium filled tube which is an exhibit and these were furnished to our opponents and they were marked for identification N and I would like to offer those in evidence.

Mr. Davis: I was under the impression that we put them in. I certainly think that they should be in. They should be in as having been furnished by the witness Kelly in response to our request and testified to by him as correct. Is that what you want?

Mr. Richmond: Yes.

(Received in evidence and marked "Defendant's Exhibit No. 328." *See Volume VI, Defendant's Exhibits, page 1364.*)

Mr. Darby: Mr. Howson offered in evidence a copy of the DeForest Patent 879,532, the grid audion patent. I have no objection to that. He also offered in evidence copy of DeForest Patent 1,201,273, applied for December 28, 1915, and issued October 17, 1916, and I object to that as being wholly without any relevancy to any issue in the case. The early DeForest patent was put in evidence, was received in evidence, but the later patent, the one which I object to was not received at the session.

(Discussion.)

The Court: I will overrule the objection. While I do not see it I think if counsel can find in it anything that they deem to negative the effect of some of your testimony then it should be available to them wherever they may want to use it.

Mr. Darby: I was merely trying to keep a large record down.

(Received in evidence and marked "Plaintiff's Exhibit No. 217." *See Volume IV, Plaintiff's Exhibits, page 328.*)

Mr. Darby: Do I understand that the plaintiff's rebuttal case is closed?

Mr. Edmonds: We are not through yet. We have another one because of your absence yesterday. We offer in evidence the file wrapper and contents of the DeForest Patent 1,507,017, applied for March 20, 1914, and granted September 22, 1924. That is for the same purppose.

Mr. Darby: I object to it for the same reason. My recollection is that this patent, the file wrapper and contents of this patent, which is one of the patents involved in the 4915 case before your Honor, according to my recollection is an exceedingly long thing, something like——

THE COURT: I remember it.

MR. DARBY: It is an enormous thing about three or four inches, to offer the file wrapper and contents of that patent in this case.

MR. EDMONDS: Nothing short of the file wrapper and contents will make our point. I will state our purpose in sixty words. Here is an original specification of an application filed in March, 1914, and it reads in this fashion: "By reason of the arrangement above described and the ionizing of the gas in the bulb due to the heated filament."

Several years later than that, to wit, November 13, 1916, that sentence was stricken out of the specification and the patent issued without it. By that time Mr. DeForest had found gas ionization was not to be used in the practical tube of the future, and he struck that out entirely. We want the benefit of that fact in this case.

THE COURT: I am wondering whether we can not get along without printing that. You may have the benefit of those statements, but use copies without enlarging the record.

MR. DARBY: Why cannot Mr. Edmonds' statement just as he has made it here be accepted without putting the file wrapper in?

MR. EDMONDS: That will answer the purpose.

MR. DARBY: Fine.

MR. EDMONDS: Do you agree to that?

MR. DARBY: I agree to having the statement go in.

THE COURT: I will overrule the objection. You have nothing else in the patent and if there is any other quotation from the patent that you want a record of made, you may do so.

Mr. Darby: My whole point is that Dr. DeForest in 1914, had the theory that all tubes operated by gas ionization and subsequently found his theory was wrong and that does not affect the fact at all. Now do I understand that the plaintiff's rebuttal case is closed?

Mr. Edmonds: There are two exhibits offered in evidence but the exhibits were not produced and we did not have an opportunity to examine a witness concerning them.

Mr. Darby: There were two exhibits, 83 and 84, which were physical exhibits that your Honor will recall we mentioned once before. The Clerk of the Court in Brooklyn assures me that he has never received those exhibits. They were mailed to him directly from California by the notary public. I sent two long telegrams to the notary public in California but thus far have been unable to get any response to them. I asked him to look up and send back to me the registered receipts of the exhibits. The only information I could get from him at all was to the effect that he mailed them to the Clerk of the Court in Brooklyn.

One of them was a DeForest audion structure, the sole function of which was to have the witnesses identify the tubes that Lamont had pumped were similar in appearance to this structure, and that structure is identical in appearance with this tube we have referred to as 7-A in the interference, that is, the tube that was left with Dr. Arnold when Dr. DeForest made the demonstration. That serves the sole purpose in the California deposition.

Exhibit 84 was a Jahnke tube which I might characterize as being a three-electrode tube of a rather freakish shape and because of the fact that it was referred to and one was available we secured one of them. If under those circumstances your Honor will permit me to withdraw those two exhibits from the case and it is acceptable to Mr. Edmonds I will do so, because they serve no useful purpose in the case and I offered them only because they were part of the deposition.

MR. EDMONDS: That is satisfactory.

THE COURT: Let them be withdrawn by agreement.

MR. DARBY: Now, does that close the case?

MR. HAIGHT: We have gone over the parts of Richardson's book that the plaintiff desires to be marked in evidence. We have no objection to the receiving in evidence of pages 13 to 15, 20 to 23; 61 to 68; 128 to 130. We do object to the admission of pages 91 to 92 and 117 to 118. The reasons why we object to those latter are these: Mr. Davis tells me that the first was read in but I do not know whether that makes it evidence. Who was it read in by?

MR. DAVIS: I read it in myself or I had one of your witnesses read it. I do not see why we need to trouble about that, Mr. Edmonds.

MR. HAIGHT: The reference in the interference record from which the offer of pages 117 to 118 is based is found on page 1259 of the interference record and is in the testimony of Dr. Langmuir. He says this: "On page 118 of Richardson's book entitled the emission of electron from hot bodies, he refers to my published results that argon"—and so forth, and then he quotes. I do not see any justification for offering any more of Richardson's book than that which is already there.

THE COURT: What have you to say, Mr. Davis?

Mr. Davis: I understand it is simply a question of getting the context, that is all, to make it clear what the situation was. It is not put in to prove anything.

The Court: Dr. Langmuir used the portions upon which he relied. Do you withdraw your offer as to——

Mr. Davis: Yes, because for the reason stated, and I understand that this book will be treated as a physical exhibit and that the only parts that are in evidence are pages that are agreed to.

The Court: The book may be used as a book of reference for those pages but no other pages are a part of the record in this case.

Mr. Davis: That is right.

(Received in evidence and marked "Plaintiff's Exhibit No. 218." *See Volume IV, Plaintiff's Exhibits, page 332.*)

Mr. Davis: In response to Mr. Darby's question as to whether we close our rebuttal, the answer is that we have closed this morning.

Mr. Darby: We have the Alexanderson patent marked for identification. I do not care about putting it in evidence unless Mr. Davis wants me to put it in.

Mr. Davis: I think it will only encumber the record.

Mr. Darby: I would like to offer in evidence as a physical exhibit the book on high vacuum by Dr. Saul Dushman, production and measurement of high vacuum.

Mr. Davis: I object.

Mr. Darby: I believe that this book should be in as a physical exhibit because your Honor will recall I cross-examined Mr. Hogan in connection with certain passages in the book and Mr. Hogan qualified his answer, or at least mentioned in his answer as to whether or not he agreed with the statement or the statements contained in the book, that he would have to know what particular state of facts, or what particular instance Dr. Dushman was talking about, in the particular case that Dr. Dushman was talking about in making that statement and my purpose of putting the book in is to establish just what particular circumstances and instances Dr. Dushman was talking about.

Mr. Davis: It seems to me highly objectionable on the same basis that I cannot put the whole Richardson book in. You cannot make a book evidence by asking a witness a question about it, of course.

Mr. Haight: I suggested to Mr. Darby that he read the argument and ruling yesterday.

The Court: I think the objection is well taken, but if there are any portions of it that are directly pertinent or material, probably your purposes will be served by following the same course that was followed with respect to the Richardson book.

Mr. Darby: Yes, sir.

Mr. Davis: I refer to your Honor's ruling just now and I may assume that Mr. Darby read to the witness the portions he regarded as important.

Mr. Darby: I read to the witness the portions I considered important.

The Court: My impression is that you are limited by that but if you think you are not I will hear you, but I should think we went through this field reasonably well yesterday and in view of that if you have not conferred with your colleagues about it——

Mr. Darby: I will not press it.

Mr. Haight: Defendant offers in evidence the tube that was demonstrated this afternoon by Dr. Arnold.

(Received in evidence and marked "Defendant's Exhibit No. 329.")

FREDERICK L. HUNTER.

Frederick L. Hunter, was called as a witness in sur-rebuttal, on behalf of the defendants, and being first duly sworn, testified as follows:

Direct Examination.

By Mr. Darby:

Q. 1. What is your age, residence and occupation, Mr. Hunter?

A. Age, thirty-one; residence, Towaco, New Jersey; employed as Engineer in charge of the Audion Division of the DeForest Radio Company.

Q. 2. You graduated from Stevens Institute?

A. Massachusetts Institute of Technology.

Q. 3. What year and what degree?

A. Class of 1919, Bachelor of Science, in the Department of Electro-Chemical Engineering.

Q. 4. You served with the staff of instructors at M. I. T.?

A. I did.

Q. 5. And then you were employed by the Western Electric Company?

A. I was.

Q. 6. In vacuum tube work?

A. Yes.

Q. 7. For how long?

A. Until 1923.

Q. 8. How long was that?

A. Approximately three years, slightly over.

Q. 9. For how long have you been with the DeForest Company?

A. Somewhat over three years.

Q. 10. All in vacuum tube work?

A. Yes.

Q. 11. In manufacturing the type of receiving tubes charged as infringements of the Langmuir patent in suit, do you use an automatic exhaust machine?

Mr. Davis: I object. This question of infringement has been covered by a stipulation. At the beginning of the case defendants stipulated that they infringed all of the claims of the first patent and certain numbered claims of the second, third and fourth patents. Our experts have not discussed infringement in any way, shape or manner and have kept away from it. It seems to me that in sur-rebuttal, whichever it is, it is too late to go into that question.

Mr. Darby: I am not going into that question. This testimony is related strictly to rebutting the testimony of the witness Hogan.

The Court: Won't you have the question read? It leads us to think that it is directed specifically to infringement.

Mr. Darby: If the question has carried that impression I will reframe it.

By Mr. Darby:

Q. 12. In the manufacture of the type of DeForest receiving tubes before the Court as infringement of the Langmuir patent No. 1 in suit, do you use an automatic exhaust machine?

Mr. Davis: Same objection.

The Court: I miss the point, Mr. Darby, because it looks to me—although the form is changed—as if it bears on the issue of infringement and could bear on the issue of infringement only.

Mr. Darby: I was merely using the word infringement to identify the tubes.

The Court: Will you tell me what your purpose is?

Mr. Darby: My purpose is to have the witness——

The Court: Let me ask you first: What is the testimony of Mr. Hogan which you are attempting to meet by this testimony?

Mr. Darby: The testimony of Mr. Hogan has two points. One is in connection with the automatic exhaust machine and his consideration of the prior art where he states, at least as I understand in effect, that you could not obtain a sufficiently high degree of vacuum——

The Court: All right. You may move to strike it out if it appears to be not relevant. I will overrule the objection with leave to move to strike out after the answer is taken.

(Question repeated.)

A. We do.

Q. 13. Will you very briefly describe the automatic exhaust machine and state the process employed in producing these tubes in their consecutive steps and the degree of vacuum obtained by the respective steps?

The Court: It being understood that this question, like the other, is not to elicit evidence touching or bearing upon the question of infringement.

Mr. Davis: I further object for this reason: The testimony of the witness Hogan as far as I remember it and as far as he remembers it was something like this. Mr. Darby asked him certain questions about automatic exhaust machines and he said he did not know.

THE COURT: Then, Mr. Darby, you will have to examine the record.

MR. DARBY: I am not confining this in any sense to a consideration of the automatic exhaust machines. I am advancing it on this proposition or this theory and I am not in any way attempting to retract from the stipulation.

THE COURT: I have that now.

MR. DARBY: Mr. Hogan has testified in one instance that blue glow, for example, would be absolutely fatal to a thoriated tungsten filament, and wipe off this layer one atom deep. He has also testified of the extreme care and pains that must be taken in considering prior art patents, to get the highest degree of vacuum where you use a thoriated tungsten filament. I want to prove by this witness in connection with my admission, that these claims are not infringements of our structure, that Mr. Hogan's consideration of this prior art is, as I view it, rather far-fetched, in view of the fact that this process in making the infringing tube is admitted to be an infringement.

MR. DAVIS: Your Honor please, all that from our point of view, is absolutely immaterial, for these reasons: In the first place, if during the manipulation of the tube in the exhaust machine, the atomic film would be burned off, that would be re-formed. You have this reactivation. In the second place, it has been brought out and brought out to the utmost degree, that where you are using those powerful keepers like magnesium that the exhaust precautions which were necessary in order to secure the result first obtained in the prior art become relatively unnecessary. I do not mean that they do not have to be taken, but you may use a preparation of the anode which would be inadequate without a keeper. It seems to me that to prove that the DeForest Company exhaust their tubes very quickly, because they take advantage of all of Dr. Langmuir's inventions, it is not a defense in suit.

Mr. Darby: But Mr. Davis is overlooking—pardon me.

The Court: I think, Mr. Davis, that will be your argument which might be advanced by you to meet this, but it does not appeal to me at the moment as an argument which denies to this testimony, admissibility; and it may be advanced to negative this fact, but it is admissible to meet the testimony of Mr. Hogan, if it will.

By Mr. Darby:

Q. 14. Will you answer the question?

Mr. Davis: I think there ought to be specific questions asked and directed to the particular point.

The Court: Yes, if it is not a specific question. Will you read the question, Mr. Smart?

(Question repeated.)

Mr. Davis: The specific process.

The Court: Let that question be withdrawn, Mr. Darby, and re-put it.

Mr. Darby: Are you referring to the automatic machine, you want a specific question as to the process employed?

Q. 15. Will you briefly state the successive steps of processing these tubes, these receiving tubes?

Mr. Davis: The same objection. If there is any merit in that question, it is to show some qualification of what Mr. Hogan said with respect to some specific steps of the process and I see no reason to go through the whole process.

Mr. Darby: It is the whole of the processes entirely, and if your Honor would care to hear me further on it.

MR. DAVIS: We would like to see the place in the record about it.

MR. DARBY: Take Mr. Hogan's testimony where he speaks of the prior art and says that this patent shows that you can produce vacua down to two to ten microns, and that is incandescent lamp vacuum, and of course that was impossible to get the vacuum necessary in these tubes. I intend to prove by this witness that we produce the tubes by the pumps down to five microns.

THE COURT: Why not direct his attention and be as near to leading questions as seem proper?

MR. DARBY: Very well.

THE COURT: Put a series of questions rather than asking him to narrate the process as a whole.

By MR. DARBY:

Q. 16. Have you got a device or tube in the form in which it is put on the automatic exhaust machine?

A. I have (producing same).

MR. DAVIS: I object. I do not see that that has anything to do with that question at all, the details of exhaust. If Mr. Darby wants to ask the witness a question to what vacuum the tube is pumped, I have no objection to that.

THE COURT: I have gathered the impression, not only from the exhibits of the prior art, but also from the mass of testimony in here, that the form in which it was put upon the exhaust machine, might be quite material as to the quality of the vacuum in the tube, upon its being sealed, and for that reason I think the objection is not well taken.

Q. 17. Is the electrode structure——

THE COURT: He has not answered the previous question.

MR. DARBY: Yes—"I have."

Q. 18. Is the electrode structure freed from gas before it is assembled in this tube?

A. It is not.

Q. 19. Are any pains taken in assembling the tube to prevent contamination of the electrodes by handling or otherwise?

A. None.

MR. DAVIS: Your Honor understands that this is all subject to this objection?

THE COURT: Yes.

Q. 20. As I understand it, this tube in the form that you have produced it, is inserted in a sleeve or receptacle with the open end of the tubular tube leading into it, is that correct?

A. That is right.

Q. 21. What is the material in which it is inserted?

A. Rubber.

Q. 22. Is it coated with any oil or material of that kind?

A. Castor oil.

Q. 23. As I understand it, it is then exhausted by a rough exhaust pump?

A. It is.

Q. 24. It is likewise enclosed in a heated oven?

A. It is, during a portion of the exhaust.

Q. 25. How long is it maintained in the heated oven?

A. Three minutes and about thirty-six seconds.

Q. 26. And throughout what portion of that three minutes and about thirty-six seconds is it connected to a pump?

A. For approximately nine seconds it is connected to a rough exhaust pump—no, approximately 1½ minutes it is connected to an exhaust pump.

Q. 27. And at any time while it is in this heated oven, is it connected to a finer pump; that is, one that can get a higher degree of vacuum than your rough pump?

A. Yes.

Q. 28. For how long?

A. For about approximately thirty-six seconds.

Q. 29. Then is anything done to remove any oil vapor that may have gotten into the tube?

A. Nothing.

Q. 30. While the tube is in the heated oven, is air allowed to pass into the tube, or deliberately fed into the tube?

A. Yes, for approximately—for at intervals which total about one and one-half minutes.

Q. 31. Is that what you call "air washing"?

A. It is.

Q. 32. And what is the purpose of the air washing?

A. The air fed into the tube is dried very carefully by means of sulphuric acid, caustic potash and phosphorus pentoxide——

Q. 33. Any means taken——

THE COURT: He has not finished.

A. (Continuing.) The purpose of that very dry air is two-fold. It takes up water vapor like a sponge, and also communicates heat from the bulb to the structure.

Q. 34. Through conduction—through the gas particles?

A. Yes.

Q. 35. Are any means thereafter taken to exclude from the bulb any gases that might result from the presence of phosphorus pentoxide?

A. No.

MR. DARBY: I offer the tube in evidence.

(Tube received in evidence and marked "Defendant's Exhibit No. 330.")

Q. 36. As I understand it then, the tube is sealed off from the exhaust pump, is that correct?

A. That is right.

Q. 37. And is the tube that I now show you, the condition of the tube? Does that illustrate the condition of the tube after it is sealed off from the pump?

A. It does.

Q. 38. And what is the order of magnitude of pressure in the tube when it is sealed off?

A. From one to eight microns.

Q. 39. I call your attention to two little white spots, one on each side of the plate electrode, in both the Exhibit No. 330 and the tube in my hand. What is that?

A. Magnesium.

Q. 40. After the tube is taken off of the automatic exhaust machine, as I understand it, you then put the tube on a base; is that correct?

A. That is correct.

Mr. Darby: I offer in evidence the tube illustrating its condition as it comes off of the machine.

(Received in evidence and marked "Defendant's Exhibit No. 331.")

Q. 41. And does the tube that I now show you show the condition of the tube after it is based?

A. It does.

Q. 42. Then I understand that you put this tube in what you call a rotary flashing machine; is that correct?

A. It is.

Q. 43. And current is supplied, or at least heat is supplied through an induction coil on this flashing machine, which heats the magnesium to a point where it volatilizes; is that correct?

A. It is.

Mr. Darby: I offer in evidence the tube based prior to volatilization of the magnesium.

(Received in evidence and marked "Defendant's Exhibit No. 332.")

Q. 44. And it is the volatilizing of the magnesium which causes the mirror-appearance to the glass of the vessel, is that correct?

A. That is true.

Q. 45. As is shown in the tube which I now have in my hand?

A. Yes.

Q. 46. Then as I understand it, you thereafter use heat treatment of the filament, and apply voltage on the plate electrode——

Mr. Davis: Now, if your Honor please, that part of it certainly can not refer to the exhaust; that must refer——

Mr. Darby: That is my last question, as I understand it, the next thing they do is heat the filament, give the filament heat treatment.

The Court: I will take your answer to that question. I think it is material. Now, then, whether it must be eliminated in weighing the issue for reasons which are obvious to both of you, is a question I will have to consider later, but I think that question is admissible, because whether that clean-up is the result of one thing or another thing, is a matter which I should not now determine.

Mr. Darby: I will defer my question.

Q. 47. Then, as I understand it, you flash the filament agent, and apply a voltage on the plate; is that correct?

A. That is.

Q. 48. And does blue glow appear when you apply a voltage on the plate?

A. Nearly always.

Q. 49. Then as I understand it, a tube is tested for its operating characteristics and it is in a condition for sale?

A. That is right.

Q. 50. After it passes the tests?

A. That is right.

Mr. Darby: I offer in evidence the tube in its completed form.

(Received in evidence and marked "Defendant's Exhibit No. 333.")

Q. 51. Have you a photograph of the automatic exhaust machine?

A. I have.

Mr. Davis: The same objection.

Q. 52. And an enlarged sectional drawing showing its structure?

A. I have.

Mr. Darby: In view of the permitted leading nature of the examination, I do not care to offer this in evidence unless opposing counsel should care to have them go in evidence. I had intended to have the witness describe the machine to permit a more complete understanding of its operation; but in view of the permitted leading nature of the questions, I do not believe it is necessary, unless you want it.

Mr. Davis: No.

Q. 53. Prior to the flashing, what was the order of magnitude of the pressure in the tube?

A. From 1 to 8 microns, depending upon the condition of the pumps.

Q. 54. And after the flashing, what was the order of magnitude of the pressure; that is, in its completed form, in the completed form of the tube, the last exhibit, after it has passed the test?

Mr. Davis: Of course it is understood these objections continue. Here is a question that goes right straight at one of the features of the patent after he has admitted infringement.

The Court: Then I made my ruling not specific or clear. These questions as I understand it are directed not at all to infringement. They pertain not at all to infringement any more than if these tubes had been manufactured by John Smith in Australia; but here are tubes manufactured in Australia, let us say, which are charged by the plaintiff to infringe the patent. These questions are all directed as it seems to me, and the evidence pertains to a denial of the effect and substance of certain portions of your expert testimony, by the production of a fact witness, and they go, as I see it, and they are neither excluded nor admitted, by reason of the fact that it happens to be the process employed by the defendant here, that has got nothing to do with it; but here are tubes produced in a certain way, alleged to infringe, which tend or do not tend, according as I take the respective contentions, to meet the testimony of an expert witness by fact, and for that reason, and not at all as bearing upon infringement, but solely as indicating the degree of vacuum that is in fact obtained and had, by a process employed by some one who happened in this case to be the defendant. Now, then, how that last production is brought about and what brings it about, is another question, which I will not pass on now.

Mr. Darby: I am not going into any theory at all.

The Court: That is how I understand your question, and I think the last question—it might under other issues, and under a different state of issues—have a bearing upon infringement, but here it has no bearing upon that. It has merely a bearing as to how the vacuum—as to whether the theory of the plaintiff's witnesses is correct, or whether it is incorrect.

The Witness: The answer to that last question was, approximately one one-thousandth of a micron.

Q. 55-56. One one-thousandth of a micron?

A. Yes.

Mr. Darby: You may cross-examine.

Cross-Examination.

By Mr. Davis:

XQ. 57. Where did you get this induction coil you speak of?

A. I do not understand the question.

XQ. 58. Where did you get this induction coil you speak of?

A. Made it.

XQ. 59. What are the dimensions of it?

A. It is just sufficient to slide over the bulb.

XQ. 60. That is, it has a coil that surrounds the bulb on the outside, is that right?

A. That is right.

XQ. 61. That is mounted on the machine?

A. That is on the mechanism on the machine.

XQ. 62. At a certain stage, the tube passes into this coil and remains there for a certain time; is that right?

A. That is right.

XQ. 63. Now, what is the magnitude of the current you send through that coil?

A. We did not measure it.

XQ. 64. What is the voltage?

A. I have no way of knowing.

XQ. 65. What is the frequency?

A. It is approximately 900 meters.

XQ. 66. That is, it is a very high frequency current?

A. Yes.

XQ. 67. Not an ordinary alternating current at all?

Mr. Darby: Mr. Davis, is that material to this case or are you trying to establish evidence in connection with the Northrak patent?

Mr. Davis: I am not interested in that patent. We are not exclusive licensees, and we have paid our royalty. I am very much interested in the fact that this thing casually referred to as an induction coil, turns out to be a high frequency electric furnace, and that I brought out.

Mr. Darby: No objection.

XQ. 68. Now how much does this high frequency furnace heat the anode?

A. That depends on the amount of gas in the tube; it varies.

XQ. 69. Let us have some limits; is it five degrees C.?

A. When the vacuum is very good, the magnesium goes off, and the plate gets a dull red.

XQ. 70. And when it is poor?

A. When it is poor, the plate gets bright red.

XQ. 71. That is, this heat is generated in the plate by currents induced in the plate by this high frequency coil on the outside?

A. That is true.

XQ. 72. And at the same time, it vaporizes the magnesium?

A. Yes, sir.

MR. DAVIS: That is all.

RE-DIRECT-EXAMINATION.

By MR. DARBY:

RDQ. 73. How long is the heat of the induction coil applied to the plate, in order to raise it to the proper degree of temperature to flash the magnesium?

A. Since the machine is automatic, it must get up to the temperature in four seconds.

RDQ. 74. And the heat is not maintained on the plate thereafter?

A. It is not.

MR. DARBY: That is all.

RE-CROSS-EXAMINATION.

By MR. DAVIS:

RXQ. 75. Where did you get your authority for calling that an induction coil; did you ever hear any one call it an induction coil?

A. I did not call it an induction coil.

RXQ. 76. I beg your pardon, you have adopted Mr. Darby's characterization.

A. I answered Mr. Darby's question.

RXQ. 77. Did you ever hear it called an induction coil, except by Mr. Darby?

A. Yes.

RXQ. 78. When?

A. It is a common terminology.

RXQ. 78a. To call it an induction coil?

A. It is a coil which operates an induction furnace.

RXQ. 79. You call that an induction furnace round the factory?

A. It has been referred to more than once.

RXQ. 80. Who did that?

A. Various members of the plant.

RXQ. 81. You know the term "induction coil" has a perfectly definite meaning in the art, don't you?

A. Yes, I know that.

RXQ. 82. Which is entirely different from this meaning, is it not?

A. I am aware of that, yes, sir.

RXQ. 83. Where did you get this 900 meter current you pass through this coil?

A. We have an oscillator.

RXQ. 84. That is a vacuum tube oscillator?

A. A vacuum tube oscillator.

RXQ. 85. Can not you give us some idea of the amount of energy?

A. We use 250 watt tubes, four of them in parallel, applying 3,000 volts on the plate.

RXQ. 86. In this oscillator?

A. Yes, sir.

Mr. Davis: That is all, Mr. Darby.

Mr. Darby: That is all, Mr. Hunter.

(Witness excused.)

Mr. Darby: I would like to offer in evidence and agree not to have it reproduced unless Mr. Davis wants to have it reproduced, the list of references which were referred to in the Interference proceeding, but concerning which no evidence has been put in here, the sole purpose of this evidence or these references is to enable your Honor to have before you the references that were testified about in the Interference proceeding in support of the motion to dissolve the Interference on the ground of patentability, and that is its sole function, to have it before your Honor.

THE COURT: Do you know whether it was before the Patent Office tribunals?

MR. DARBY: The one tribunal, the Law Examiner, that is the only tribunal who passes on the question of patentability, and that is not including the Armstrong article. Mr. Davis has somewhere in the record made reference to the fact that Mr. Hogan has not testified to these references because we have not put them in, but we have no intention of putting them in except for that one purpose.

MR. DAVIS: If your Honor please, it is a little unusual, and I rather dislike to admit a lot of references that even yet we have not seen, we have seen extracts from them.

(Discussion.)

MR. DARBY: I am perfectly willing to withdraw them.

MR. DAVIS: I do not know what is in them. I ought to know because I ought to have known years ago and maybe I may be blamed for not knowing, but I dislike to have them gone in after our expert has gone off the stand.

THE COURT: Then they are withdrawn.

MR. DARBY: Yes. That completes our case.

MR. DAVIS: Then I have two witnesses in rebuttal.

PLAINTIFF'S SUR-REBUTTAL PROOFS.

FAIRFAX BAYARD.

Fairfax Bayard, was called as a witness in surrebuttal on behalf of the plaintiff, having been duly sworn, testified as follows:

Direct Examination.

By Mr. Davis:

Q. 1. You are an attorney connected with the Patent Department of the General Electric Company?

A. I am.

Q. 2. And you were in the United States Patent Office?

A. I was.

Q. 3. For how long?

A. About twenty-five years.

Q. 4. And when you left what position did you occupy there?

A. Examiner in Chief, member of the Board of Examiners in Chief.

Q. 5. For how long?

A. Ten years.

Q. 6. And prior to that time you had been what?

A. I had been Examiner of Interferences for three years and Law Clerk assisting the Commissioner for three years.

Q. 7. That is sufficient, I think. When a man has an application in the Patent Office and a patent issues to another with claims which seem to the applicant to cover his invention or to be capable of being construed to cover his invention, what is the remedy which the applicant has, what is it the practice in the Patent Office that he should do?

A. He should copy the claims of the patent which he considers to interfere and ask for an interference proceeding.

Q. 8. By copy you mean introduce them into his application?

A. I mean he should file an amendment to his application directing the insertion of these claims which he embodies in his amendment, copied from the patent.

Q. 9. Suppose he thinks they are badly expressed or unscientifically expressed, what is his remedy?

A. There is no direct remedy at that time. He copies the claims anyhow and gets the Interference.

Q. 10. That is what I want. He copies the claims to get the interference. How long has that been the practice?

A. For about twenty-five years. It was inaugurated about 1900.

Mr. Davis: That is all.

Cross-Examination.

By Mr. Ballard:

XQ. 11. Don't you know that the Patent Office decisions of the Commissioner, in control of the office, and the practice provide for interferences between applicants and patentees where the applicant cannot copy the exact language of the claims of the patent?

A. I am not aware of any rule bearing on that subject. As to decisions, I remember that there was a decision, *ex parte* Card & Card, in which the question was discussed, a good many years ago, in an interference in those cases where the patent is limited to some detail of invention which the applicant has not disclosed and therefore cannot properly claim. I remember that there was some discussion about that.

XQ. 12. Do you remember the decision in *ex parte* Thompson?

A. No, I do not recall the decision in *ex parte* Thompson.

XQ. 13. You do not think there is anything in the Patent Office rules or practice that requires any applicant to copy any claim that does not properly describe his invention?

A. I do not think that any applicant is required to copy a claim which in his opinion cannot be construed to cover his invention.

Mr. Ballard: That is all.

Mr. Davis: That is all.

(Witness excused.)

IRVING LANGMUIR.

Irving Langmuir, was called as a witness in surrebuttal on behalf of the plaintiff, and having been previously sworn, testified further as follows:

Direct Examination.

By Mr. Davis:

Q. 1. You have just heard, have you not, described certain operations of pumping a vacuum in a tube as practiced by the DeForest Company?

A. Yes.

Q. 2. Will you please explain how it happened, what the physical causes were, that that vacuum which was testified at one time, when the tube was sealed off from the pump, was several microns, was reduced to one one-thousandth of a micron and how that could be under the circumstances, and describe how that could be in the presence of stop-cock greases and so forth?

A. It is made possible by the effectiveness of magnesium in producing and maintaining high vacuum and by the effectiveness of the very useful method of heating electrodes which has become possible by high frequency currents applied by induction coils, currents induced in the metal parts of the electrodes.

By placing a coil around the tube and passing a very heavy high frequency through it, in this case from a high frequency generator of about one kilowatt, and a frequency of about 30,000 cycles per second, a radio frequency, and large currents, it is possible to heat the objects placed in that coil almost instantly to red heat. For instance a coin or a pen held in the hand and inserted into this coil almost immediately becomes red hot by the currents set up in the metal part by the induced voltages from these high frequency currents.

That I think is used today for practically all vacuum tube exhaust because it has this enormous advantage that you can heat the plate to a red heat or white heat almost instantly and keep it there as long as desired and drive the gas out very rapidly out of the red hot plates without at the same time injuring the filament in the slightest degree.

By the old methods that were necessary, before that method was possible, in order to heat the plates red hot it was necessary to proceed by an extremely laborious process. The plates contained gas and you had a relatively small filament, and you would light the filament and put voltage on the plate and you would get a few milliamperes of current but you could not safely use very high voltages because the first gas that would come out would be ionized by the electron current and would produce positive ion bombardment of the filaments. That would injure the filaments unless you applied only a little voltage and a little current at first and waited for the pump to pump out that gas. This process had to be repeated again and again and again and probably in the older days it was a matter of hundreds of times, applying voltages and each time a little higher current and waiting for the pump to remove the gas.

That was necessary because if you heated the plate all at once at any time you got such a large amount of gas. In order to heat the plate you would have to have large currents and high voltages, both were necessary for even on small tubes it was a question of ten watts or so, of energy that needed to be liberated on the surface of the anode.

If you should get all that gas out at once you would get such severe positive ion bombardment that it would destroy your filaments in a few seconds or minutes. Thus unless you used great care the life of the filament was practically gone.

By this new method we get all that gas out without calling on the filament to emit any electrons at all. You can drive it all out of the electrodes at once in a very short time and if the device is still connected to the pump it could be pumped out. This is usually done with the larger tubes, the process being applied while the tube is on the pump and then you get rid of the gas in the electrodes in one operation and after that you can get the gas out of the filament and out of the grid.

But in this case the tube had been sealed off from the pumping system, before this process was carried on; and there was one to eight microns of gas left in the tube. The tube had been heated to get moisture out of the glass but only for a short time and the degree to which the walls were denuded from water vapor and carbon dioxide and nitrogen was nowhere near what would have been necessary in the old days, because now magnesium would take care of any slight traces of water vapor or carbon dioxide that might come off subsequently from the walls. Thus it was unnecessary to go to extreme methods of exhaust. In this case there was a little residual gas. That gas at eight microns pressure was probably hardly 1 per cent. of the gas that would come out of the electrodes during heating. It did not make any difference whether it was one or eight microns left in the tube. It would not have been material. It was just a little more gas that would be taken care of by the magnesium anyway.

Then in this particular case that we are referring to the plates were heated to very high temperature by this induction method and the gas was driven out and at the same time the magnesium was also heated by the same induction and was vaporized at the same time. All of those gases that come off from the plate are gases that can combine with magnesium under the conditions where the magnesium is in the form of a vapor.

Then the magnesium forms a film over the surface of that bulb which is and remains extremely active during the whole life of the tube in cleaning up and removing any further traces of gas that may come off the electrodes or may come from underneath the deposits of magnesium, as for example, from the glass.

Those are the two methods combined in this case that have made it possible to accomplish in a few minutes an exhaust which would otherwise in 1912 have taken days. To have exhausted a tube like that, in 1912 would have taken say two or three days and then we would have had to know how to do it even then; I do not know that anybody knew how to exhaust a tube of that character in 1912.

I did not know and I did not learn it until very late in 1913, how to get metal plates of that size and character free from gas by the bombardment of the plates. And then, as a practical matter, it only became possible to do that by the use of the very rapidly acting pumps that we then had, by the Gaede molecular pumps—with the old pumps we had to pump by hand—and I may say the Gaede molecular pumps operated about thirty times as fast as the old Gaede rotary pump.

This makes it possible to cut down the time of the exhaust manifold (under these conditions where you are getting gases off the electrodes and have to wait for the gas to come out before you can apply the voltage again), as compared with the Toepler pump. The Toepler pump pumped fifteen or twenty cubic centimeters per second. It was a hand-operating pump. With the Gaede molecular pump you got 3000 cubic centimeters per second. Think of that ratio. It was 200 to one. of that order of magnitude.

Q. 3. Coming now to Dr. Becker, do you agree with Dr. Becker in the statement which he made about the conditions in what he called the first stage of the tube of August, 1912?

A. Yes, substantially.

Q. 4. Do you wish to add anything to the statements he made? Can you add anything to the statements that he made about it that is important to this case?

A. In the first stage the current is limited by the emission from the filament and as Dr. Becker said the whole potential difference between the cathode and the anode at the higher gas pressures, at least, is concentrated in a thin layer of gas very close to the surface of the cathode in which there is a positive ion space charge; whereas, in high vacuum tubes we have an electron space charge.

There is a positive ion space charge within the distance of a few tenths of a millimeter from the cathode under the conditions that he is speaking of, and then the gas through probably 99 per cent. of the volume of the bulb, or 95 per cent. of the volume of the bulb at least at the higher gas pressures, the space is very nearly free from electric field, that is, there is very little potential gradient.

The space is nearly all at the same voltage and at about the same potential as the anode. It may differ by a few volts.

The walls of the tube are always negatively charged with respect to the bulk of the gas. There is a little thin layer close to the surface of the walls where there is also a little positive ion space charge and that causes a little drop in potential, five volts in the case that Dr. Becker spoke of, but as the pressure is lowered the supply of positive ions decreases, there being less gas to ionize, and the positive ions are no longer able to keep the walls from charging negatively.

The reason the walls charge negatively is because the electrons. All through the space, in this field free space, there are equal numbers of electrons and positive ions per unit volume and there is thus no space charge, but the electrons are moving very fast and the positive ions are moving slowly so that the electrons carry a much bigger current.

More electrons per second tend to strike the walls than the positive ions and that electron current is compensated for by the supply of positives. If that is no longer sufficient then the walls become more and more negative and as Dr. Becker said, they went down to fifteen volts at the end of stage 1, just before the stage 2 starts.

So we have in the tube no space charge through most of the gas, and a thin layer of positive space charge surrounding the cathode and surrounding all surfaces of the glass.

There is one other point, and that is that in this case the electrons acquire nearly all their speed in passing through this little thin layer on the surface of the cathode and they then have their full energy corresponding to 250 volts or 245 volts, if there is 250 volts on the anode, and they travel in straight lines until they are stopped by something, either by collisions or by coming close to the glass walls in this little region where there is a strong field.

The electrons striking the glass walls will be reflected, a good many of them, and thrown back into the gas and they travel around in the gas until they ionize, in general, gas molecules. The electrons then lose energy and new electrons are produced and those scondary electrons, those lower velocity electrons are the ones which ultimately reach the anode and carry the current. The energy of the discharge is not liberated on the surface of the anode in this type of a discharge, but it is liberated on the walls of the tube.

The positive ions that are formed are formed in a region where there is very little electric field and although they move at velocities of many miles a second they move at velocities that are almost negligible as compared with the velocity of the electrons. The result is they are very effective in eliminating space charge. Those positive ions ultimately, practically all of them go to the walls.

In this particular device where the cathode was so small compared to the walls only a very minute fraction of them would strike the surface of the cathode. Most of them go to the walls of the tube and they are neutralized by electrons that also strike the walls. Practically none of the positive ions combine with the electrons at these pressures in the space. There is no appreciable amount of recombination of ions at pressures of a few microns in tubes of this character.

Q. 5. Now, will you consider what Dr. Becker called the third stage and stage your view of the phenomenon which goes on in that stage?

A. The main characteristic of the discharge is the third stage is that the currents are limited by space charge. There is no cathode drop, there is a slight retarding field in the surface of the cathode and the main characteristic of this type of discharge is that practically throughout the whole space in the bulb there are electric fields, very strong electric fields in general.

That is due to the fact that there are electric charges due to the space charge which set up those fields and the fields are due to the electric charges in the space in accordance with Poisson's equation.

Now I would like to discuss the distribution of this potential between the anode and the cathode. In this device we are dealing with cathodes and anodes that are geometrically alike. They are both filaments of the same size, symmetrically placed within the bulb and you can analyze the problem in this way. First of all you can consider what the distribution of potential would be if you had say 250 volts on one of these electrodes, say the anode and zero volts on the cathode, but the cathode is cold, so that it is emitting no electrons. Let us consider that we are dealing with a cold cathode and anode at 250 volts and we put the wall of the tube at the potential half-way between, that is 125 volts. Then the geometrical similarity of the two electrodes tells us that the field of the anode and cathode will be alike; that is in this case where we have no space charge. Now, if we then lower the wall potential to say plus four volts, which is the potential that Dr. Becker found in the beginning of the second stage——

Q. 6. You are in the third stage, Doctor.

A. (Continuing): —beginning at the third stage, I beg your pardon, if we change the potential of the walls from 125 volts to four volts positive, the effect of that change is to greatly increase the field around the anode and greatly decrease the field around the cathode.

Now, then, I have neglected to take into account the effect of space change. In general, if we have a symmetrical structure, as for instance, two parallel plates with the field between them, the effect of the space-charge is to give a high field at the anode, and decrease the field at the cathode, and this effect will take place in this tube. The effect of the space charge will be in general to still further increase the field near the anode and decrease it near the cathode.

This space charge effect is in this case furthermore exaggerated because of the fact that the electrons from the cathode are accelerated outward as soon as they get a little distance out past this small retarding field at the cathode, and travel out for short distances in nearly straight lines, and therefore rapidly get out of the field of the cathode what field there is. But then, in approaching the anode, they follow very crooked paths, more complicated than that of a comet coming into the solar system. They will describe orbits around these anode wires, and they may pass probably ten to fifty times around the wires, before they finally hit them by accident. They may circulate relatively long distances, and many times, before they finally strike the anode. Thus an electron may come almost to the anode, and then be thrown out into the outer regions of the bulb, and drift around relatively slowly and again come back and go very fast as it approaches the anode and is thrown out again by the field, somewhat as the comet approaches the sun.

The effect of that is that the electrons have great difficulty in getting towards the anode, but have no difficulty in getting away from the cathode. That exaggerates still further the space charge near the anode. Thus all these factors combine or act in the same direction, and I know no factor that would compensate for them. So that I conclude that in a device of this character, the field near the anode is many times stronger than the field near the cathode, and even at distances of several millimeters, or a few millimeters from the cathode and anode, that comparison holds.

Now, the walls of the tube tend to be negatively charged by the electrons from the filament and if there were no positive ions they would always charge up to a potential negative with respect to the cathode, but if there are some positive ions, these will tend to raise that potential until a balance is reached between the number of positive ions and the number of electrons that strike the walls.

Let us consider what the paths of the electrons are. The electron starts out from the cathode, moving very slowly, is accelerated by a relatively weak field, comes out into the larger volume of the bulb, and by that time probably has only a relatively small fraction of energy that it will have by the time that it gets to the anode. The result is there will be practically no ionization. I believe, in a tube of this character, when the current is limited by space charge in what is called the third stage, that throughout probably over 95 per cent. of the volume of the bulb there is no ionization whatever; that is, no ions are being produced by impact of electrons and gas molecules. There are certain numbers of positive ions in the space, but these are produced by collisions that take place relatively close to the anode.

Now, when they are produced close to the anode, they are produced in a region where there is the strongest field in the whole tube, and they are accelerated radially outwards from the anode, and are thrown out as quickly as possible from the region of the anode, and they are projected outward into a region where there is a relatively weak field, and thrown against the bulb. They are not directed towards the cathode, they are directed away from the anode, and only a few are headed towards the cathode.

The result is that of these positive ions that are thus formed, relatively few or only a negligible fraction of them get into the region close to the cathode.

Now, the effect of positive ions on space charge is most marked near the cathode. That is, if equal numbers of positive ions were introduced near the cathode or anode, other things being similar, the effect of positive ions in modifying current limited to space charge, is much greater where the electrons are near the cathode than it is when they are near the anode.

So that in this case, the fact that the positive ions are drawn on to the walls of the tube and in general, away from the cathode, means that the structure of a tube of this kind is particularly favorable. In fact, I can not think of a tube that would be more favorable in its design for suppressing the effect of positive ions in neutralizing space charge, than a tube of this character.

By Mr. Davis:

Q. 7. Can you compare the conditions in that respect, Doctor, in this tube, with the conditions in the ordinary radio tubes, and if you will, you might mention in that connection any other tubes you know of in which the reverse effect occurs in an exaggerated degree, for illustration.

Mr. Haight: I do not see how that will be rebuttal of anything that Dr. Becker has talked about; maybe I am wrong.

The Court: I will hear you, Mr. Davis, on your impression after discussion.

(Discussion.)

The Court: Will you read the question, Mr. Smart? (Question repeated as recorded.) I think, Mr. Davis, that is going back into your rebuttal.

Mr. Davis: I will withdraw the question, if your Honor please.

The Witness: I have not quite finished the last answer.

MR. DAVIS: I am sorry, Dr. Langmuir, if I interrupted you. I withdraw the question and ask the witness to finish his last answer.

THE WITNESS (continuing): I was speaking of the effect of this charge on the bulb with four volts, and it was stated by Dr. Becker that as the vacuum got better that changed gradually to a potential of something negative with respect to the negative end of the filament.

It is my opinion that the greater part, if not practically all of the reduction in current that takes place between the end of the second stage, and the lowest pressures or that would have taken place if the pressure had gone down to practically nothing, was due not to the effect of positive ions on the space charge in the tube, for I think that the positive ions are altogether too effectively removed by these fields that I have spoken of, to contribute appreciably to the space charge.

I think that the effect is probably almost entirely due to the changes in the bulb potential that result from the decreased supply of positive ions, as the pressure goes down. That has an amplifying effect and the small changes in the potential of the walls due to the change in the supply of positive ions will react back on the discharge between the anode and cathode and modify it.

Q. 8. I think you have a copy there, Doctor, of
2 Defendant's Exhibit No. 295. Will you please refer
to that copy and tell me whether or not you agree with
the statement, and if you disagree, please give your
reasons, which statement is printed or lettered on this
Exhibit No. 295:

> "If discharge had been substantially unaffected by positive ionization, the characteristic would have been within these bounds."

A. I have analyzed the experimental results in Experiment 291, which I think is in Plaintiff's Exhibit No. 99 in this case, and which are the data upon which the Defendant's Exhibit No. 295 are based. I have compared these data with the curves which Dr. Becker has given in Defendant's Exhibits Nos. 297 and 299, and I believe from these data that Dr. Becker has greatly exaggerated the change in current that would have resulted if the pressure had been lowered to a point where the further reduction of pressure would have had no appreciable effect.

This conclusion is based upon a re-examination of all the data, and I will try to give it as briefly as I can.

On a curve which I have here, which I have prepared, I have tabulated——

THE COURT: Can you all come up closer so that all of us can see it?

A. (Continuing.) I have repeated the table that Dr. Becker gave on the lower right-hand corner of Exhibit No. 295, using the same reference letters that he has, A, A-1, and so on, I have checked over the pressures that he has given, with two exceptions.

For the points C-1 and C-2, I have made a slight modification. For C-1, Dr. Becker gave the pressure 0.71 to 0.51. I think I can state very definitely that the pressure is .61, because I know the conditions under which the data were taken. I find by reference to this page of the notebook 1179——

MR. DAVIS: Just a minute, Doctor. I am afraid that won't be clear; that is Plaintiff's Exhibit No. 99.

THE WITNESS: No. 99.

THE CLERK: In this case No. 79.

A. That this current reading which is 3.9 milliamperes was taken at 2.20 o'clock, and with a gauge reading, was taken at 2.18, and one was taken at 2.21. These gauge readings were taken by Mr. Sweetser with watch in hand at exactly even minutes. The gauge was closed, or the mercury was raised exactly on the even minute, and it took about 35 seconds to take a gauge reading. The reading that was taken at the end of that time was, of course, entered up as the pressure at the beginning of that minute, so that they were taken with perfect regularity.

Now, I have simply taken the pressure two-thirds of the way between 2.18 and 2.21, because the pressure was decreasing at a steady rate, so that at 2.20, the pressure should have been two-thirds of the way between the pressures calculated preceding, and the subsequent reading, and that gives a pressure of 0.61 micron.

Now, in a similar way, I have gone back to the original data to get the values of the currents in milliamperes, because the original data are somewhat more accurate than the milliampere readings which were obtained from the original reading, by dividing by 16.5. The corrections are small, but I believe well worth making. So I have taken the original readings and have divided them by 16.5, instead of having taken the rougher calculations that Sweetser made, only using two figures, when he might have used three. The accuracy of the readings was in many cases to three significant figures. These are not very important changes.

Now, I have observed that in the two plots of the data with nitrogen, which Dr. Becker gave on Exhibits 297 and 299—and I can agree that are the data that are obtained from experiment 291, and which are plotted in his Exhibit No. 299—I find by examination of the lower ends of these curves, and for quite a distance along them, in fact, that they are quite well represented by parabolas. And if that is the case then in extrapolating to lower pressures—that is, in order to try to form an opinion as to what the current would have been if the pressure had been zero, (which is really what Dr. Becker attempts to do from these data), that the proper procedure is to extrapolate on a curve, obtained by plotting the current against the square of the pressure.

Now, I have produced two curves which are rather rough plots, but I think are substantially right. They are not as well drawn as they might be, but good enough, I think, to illustrate the point. I will mark the first curve sheet I referred to sheet A, and will mark the second one sheet B, and I will mark the third one, which I am going to refer to in a moment sheet C.

Now, the sheet B has been prepared from the data given from Dr. Becker in Exhibit No. 299.

On Sheet B, there were four curves marked A, B, C and D. Curve A is of the data that I have given for nitrogen on Exhibit No. 299, and D, is a parabola drawn to fit these points approximately. I think they fit them about as well as the experimental points do. At any rate sufficiently close for the purposes I have in mind.

If, on the other hand, instead of taking these two curves, I had plotted the squares on the pressures against the currents, then I would have obtained curves C and B, and for these curves the abscissa plotted at the top of the sheet should be used. Curve D then becomes a straight line, and curve B, which is obtained from experimental results, does not depart very greatly from the straight line.

I have done in Sheet C, the same thing, but the data are taken from Exhibit No. 297. I think these are self-explanatory, and there is a description on the sheet as to how the data were obtained. I think the fact that the experimental points fit as well as they do on a parabola mean that for the purpose of extrapolation, it is much better to use a plot against the square of the pressure, because it is much easier that way.

Now, the reason that I have done this, that I have gone back to analyze the data in this way, was that it was very apparent to me from even a preliminary examination of the data, that Dr. Becker produced, namely, of Exhibit No. 297, that the effect he obtained in his approximate duplicate tube of the variation of the current with pressure, was very much greater than that which I obtained in the experiments in August, and which were shown in this table, which is on the sheet A.

Now, for example, to make this clear: It should be noticed that in Exhibit No. 297, the highest pressure that was used and recorded was less than 0.3 micron, and the current was then about twice as great as it was with the best vacuum obtained.

Now, if we extrapolate on that curve in any reasonable way, for instance, if we use the parabolic extrapolation, we would find that the current would be close to three times as great at 0.5 micron, as it was at 0.3 micron. Well, now, referring to the data obtained in the experiment of August, 1912, it is very clear that the current, when the pressure fell from about 0.5 to 0.3 micron, that the changes were at the most, 20 per cent., instead of in the ratio of one to three; and for that reason, it seemed to me that we should use the data themselves in order to extrapolate back to the zero pressure rather than use data that were obtained in another experiment, especially when I would like to show later that conditions that would be hard to reproduce, may well affect the particular relationship, the quantitative relationship that exists between the current and the pressure in a tube of this character.

For this reason, therefore, I have plotted on sheet A all the currents corresponding to all the points on sheet A against the square of the pressure and

I have marked on the sheet the points and labeled each point.

Taking the point corresponding to B and C, there are four of these points altogether, plotted at the lower part of the curve, corresponding to the readings taken at 200 volts. It is seen that these four points, particularly the corresponding ones taken under similar conditions, give a very flat curve.

Whether we take B-1 and B-2, or whether we take C-1 and C-3, it does not make a great deal of difference in the result, and particularly taking the lower values under corresponding conditions such as C-1 and C-3, extrapolating back we find a current of 2.8 milliamperes as the current that you would have in high vacuum, which is only about five per cent lower than the observed readings C-3.

In other words, I believe from these data that if the pressure observed at point C-3 where the pressure was 0.43 micron had been lowered down to 0.1 micron or a few hundredths of a micron, the current would have gone down about five per cent. And I think that that change would been due almost entirely to the changes in the potential of the bulb and not to the effect of ~~ions~~ on the electron space charge.

Taking the data obtained at 250 volts we must consider first of all that these data are much less accurate because they were taken with a milliammeter and the readings were very small and they were only recorded apparently to the nearest half a milliampere so that the points do not lie as definitely on a regular curve as the upper ones.

Since several points were obtained at the highest pressure, that is, two points at A_0 and A_1 at a pressure of about a little over 0.5 micron, and taking the lowest pressure recorded where the current is four milliamperes and drawing a line between those two on the straight line plot, the current for zero pressure should be about 3.5 milliamperes.

However, if we take about the highest line which seems reasonable it might be about 4.6. So that we have an uncertainty somewhere between 3.5 to 4.6 as the probable range of current where the data should have come if the vacuum had been very much higher than it was.

This range of 3.5 to 4.6 extends beyond the range taken by the lowest points observed so that it is unlikely that the higher value (4.6) is to be considered as reliable.

On this Exhibit 295 the range that I have just spoken of would come at 250 volts from 3.5 milliamperes up to 4.6. That is the range which you calculate here which is far above the range given by Dr. Becker as the range that he estimated would have obtained if the vacuum had been higher.

If we take the lower point as the one that is best established, that is, at the lower voltage around 200 volts, that point comes at about 205 volts and 2.8 milliamperes, and if you take that point and assume that the current is according to the 3/2 power law, we find the point at 200 volts should be at 3.8 milliamperes and that comes within the limitation of uncertainty.

Q. 9. Referring now to Defendant's Exhibit 298 which was also one of Dr. Becker's curve sheets, do you find the alleged variation with pressure variation of current limited by space charge a normal characteristic of the tube in question and will you please discuss that?

A. Dr. Becker has quite correctly taken the data that was recorded in Experiment 317, Plaintiff's Exhibit 100, and has shown that as the filament temperature was raised the currents became constant above a certain temperature and he has concluded that these currents are limited by space charge.

He pointed out that in one case, curve 6, the current was over five times as great as it would have been at the same voltage with a high vacuum, with the same voltage on the electrodes.

I believe that this high value of five for this ratio was only possible in these runs because of the high series resistance of 16,500 ohms; in fact, I know that that must have been a very important factor and it is the reason that the values were as high as this. I have analyzed through the experimental data and find I think conclusive evidence that this factor was very important in these runs.

Mr. Davis: Dr. Langmuir, permit me to interrupt you. I would like to offer in evidence, if I may, the three plots referred to by the witness in his last answer which he lettered respectively A, B and C.

(Received in evidence and marked respectively "Plaintiff's Exhibits 219-A, 219-B and 219-C." *See Volume IV, Plaintiff's Exhibits, pages 358-360.*)

A. (Continued): I believe that the series resistance in this case functioned in accordance with the principle that was utilized by Dr. Arnold in the patent that has been referred to in this case where the presence of the series resistance stabilized the discharge so that the blue glow did not occur.

Now, I would like to explain how in this case the resistance was effective and just what effect it did have.

I have taken from the data of experiment 317 the runs that were made with nitrogen at various pressures and that are recorded at 1399 to 1403 of the record sheets.

There are not a great many points but the points enable us to conclude that the observed currents which were limited by space charge, that is, space charge in this case modified or influenced by charges on the wall which I believe is the main factor, that these currents varied with the voltage in the way that I have shown in the curve that I now call sheet D.

D

Mr. Davis: Which sheet I now offer in evidence.

(Received in evidence and marked "Plaintiff's Exhibit No. 220." *See Volume IV, Plaintiff's Exhibits, page 361.*)

A. (Continued): There are several points that are not recorded here that were obtained with very good vacuum, that is, with pressures in some cases, of considerably less than 0.1 micron and in some cases a little over 0.1 micron which were not recorded but which were used to draw the 3/2 power line which I have marked by the curve C on this plot. There were points around 100 volts and points up around 190 volts or 180 volts and they agreed excellently with the 3/2 power law.

It is very evident that if we go down to voltages close to ionizing voltages there will be very little ionization no matter what the gas pressure would be. That small amount of ionization, whether it led to a change in the wall potential or led to a modification of the space charge, in either case would not have any material effect so that the current voltage curves that are obtained for any given pressure, should all join the high vacuum curve at voltages in the neighborhood of the ionization voltage.

Take for instance when the pressure of nitrogen was from 1.0 to 1.1 micron. There are three points, one at about 100 volts, one at about a little over 120 and one at about 136 volts. Those three points show a rise above the 3/2 power law so that the current is going up considerably steeper than the 3/2 power law.

With six-tenths of a micron there are two points again which enable us to draw a curve the dotted portions of which I have drawn by extrapolation; more or less guessed at them, but I believe in a reasonable way and in a way that is in accord with other experiments I made at different times.

The curve that I have marked at about 0.3 micron has no observed points and I have simply interpolated between the curves at 0.6 micron, and the highest vacuum curves, and I meant to do it according to the parabolic law. Thus the pressure being about half-way between those two and I took the current increments about one-quarter as great. It is only a rough estimate anyway.

The observed points were of two kinds, some were taken at 250 volts and some were taken with 125 volts as line voltage, but there was a resistance of 16,500 ohms in the series so that the actual voltage on the anode fell off according to the dotted line which I have marked E in one case on the 250-volt potentials and F when 125 volts was used.

At the pressure of 1.8 microns, I only have one point and that point was not on a flat top curve so that I am not very sure of its exact position, but I believe it is substantially right.

I believe from various things that I have observed in more recent experiments that at higher pressures the curve should not rise the way I had originally drawn curve A, passing through the point of 1.8 microns but should bend back, that is, should go as I have drawn curve B, should bend backwards at a certain point.

Actually such a curve as that can never be observed experimentally except by putting in series resistance and I have made many such measurements of "negative resistance characteristics" of gassy tubes and have even used such tube as a method of producing oscillations and have studied them in great detail.

Although I have no proof in this regard, it is my opinion that several of these curves should bend back at the upper ends and I believe further that they bend back at a value of current which is about twice the value that you would get in high vacuum, I believe that without resistance you can only get about twice as high a current as you would get in a perfect vacuum.

By the introduction of gas in a tube such as that which was used in August, you can only go to about twice that value of current unless you put in a high series resistance in order to stabilize that discharge and thus enable you to balance out the negative resistance of the voltampere characteristic.

I do not know that I can make this any clearer and perhaps it is not worth while, but the point I wish to make is that from these considerations and from experience I have had with the negative characteristics I know the importance of a series resistance and I know that from this tube, the curves for which were shown by Dr. Becker (where in Exhibit 298 such large ratios as five to one were obtained), it would not have been possible to obtain such large increases in current if a definite voltage had been applied to the anode. They have only been possible by the use of a large series resistance.

Q. 10. Have you completed your discussion of the effect of gas in limiting space charge as affected by voltage, is that fully completed?

A. There is just one further point and that is there is a relation between what I have just said and what I have said in the preceding answer. From these data, the curve which I have drawn at 0.3 micron, which I believe to be reasonable, would indicate that at 250 volts, the current I believe would have gone up about 30 per cent., this is not the device of August, it is the device of experiment 317 which was very much like it, except it had a smaller bulb. At 200 volts the current would have gone up only a little over 10 per cent. as the result of 0.3 micron as compared to what it would have been in high vacuum.

Those increments are of the same order of magnitude as the values that I have discussed in the preceding answer where I found that values of 5 or 10 per cent. or so below the lowest points recorded would have been the values corresponding to the highest vacuum.

I believe in that connection that this way of getting at the data is much better than following the suggestion made by Dr. Becker when he tried to compare the two curves of Exhibits 297 and 299. He said that the distance between the electrodes in Experiment 317 was 3 millimeters and in 291 it was about 12 millimeters. He is right when he suggested that that three millimeters was at the tip of the filament. The effective distance between the filaments would be very much more than that because at the upper end the filaments were probably half an inch apart or 12 millimeters.

Dr. Becker, I think, overemphasized the cooling effect of the leads which would extend not over 10 per cent. of the way along the filament, not very far down from the leads, so that the electrons were emitted in large numbers nearly all along the length of the filament.

Dr. Becker suggested that by having the filament further—he took the illustration of its being four times as far in one case as in the other, that therefore you would get something like four times as much ionization in one case as in the other. That does not apply at all to a device of this character.

If you had a filament between two parallel plates as you have more or less in the radio tubes, the electrons that come out of the filament go to the anode and terminate on the anode surface after having travelled about the distance between the anode and the cathode. But in this case they formed orbits around it and I have no way of telling how the lengths of the orbits varied as the distance between the filaments increased or how much greater the chances of ionization became when the distance between the two electrodes is increased from 3 millimeters or 10 or 12 millimeters. In any case the electrons travel many times the distance between the electrodes and I believe that the amount of ionization would be relatively uninfluenced by the distance between the electrodes. I see no reason why the data of experiment 317 for the effect of gas should not be comparable with that of 291.

I do not know just what effect the bulb size would have. The data as far as I can examine them seem to indicate that the effect of gas pressure in the August experiment, 291, was a little less than it was in the experiment of November and December, 317.

Q. 11. Were you present this afternoon when Dr. Arnold demonstrated the tube in blue glow?

A. Yes.

Q. 12. Do you consider that the blue glow which was present when the tungsten filament was lighted or was functioning was the same as that which was present when the Wehnelt filament was functioning?

A. No, I do not think it was.

Q. 13. Please state your reasons.

A. In the first place I was not able to see any blue glow at all, and I believe I would have been able to see blue glow if there were as much as there was in the other case. In looking at the construction of the tube, and besides the effect that was spoken of, that the current was only about three-quarters as great with the tungsten filament as with the Wehnelt oxide——

Q. 14. And by current you mean space current?

A. Yes, it seems to me that it is one factor that I would expect at least to be of vital importance in determining a difference between the discharge in these two cases.

The tungsten filament is a three mil. wire in the form of a V, very small wire in the form of a V. The Wehnelt cathode is in the form of a ribbon which is over one-sixteenth of an inch wide, about that, maybe a little more, flat as a ribbon, which is also bent in the form of a V, parallel to the V of the tungsten filament, but the plane of the ribbon is perpendicular to the plates.

As I have said, I think several times already, at these high gas pressures where space charge is eliminated (and it certainly would be in the neighborhood of the electrodes in a device like this with eight microns of argon) there would be a very thin layer over the surface of the cathode in which the cathode drop occurs. In the case of the small tungsten wire that will be a little cylinder surrounding the filament in which there is a large positive ion space charge, and in the case of the ribbon it would take the form of a little thin, flat layer over each of the two faces of the ribbon. The electrons acquire their velocity, practically corresponding to the anode potential, in traveling this minute distance close to the cathode.

In the case of the tungsten filament the electrons are thrown radially out from the filament in all directions, so that a very large fraction of those—the filaments are more or less vertical and from each leg of that filament the electrons are thrown out in all directions and about three-quarters of those electrons will strike the anode traveling a distance not much more than half the distance between the plates. In other words, they will travel six or seven millimeters on the average before they strike one of the plates. A few of those electrons will escape out between the plates and they will go out into the gas and travel along straight lines until they either collide with gas molecules or become acted upon by the field which is close to the glass and thus return back into the discharge, so that ultimately they either reach the anode, or other electrons which are produced by ionization take their place and reach the anode.

In the case of the Wehnelt cathode the sheath will be a little thin, flat layer over each leg of the ribbon filament. The electrons will be projected in a direction parallel to the plate. Practically none of the electrons that get out of that filament will go straight to the plate, they will all move at first at right angles to it, projected out in a perfectly definite path and they will have to go back across the tube a good many times before they can possibly strike the anode.

Therefore the average distance that the electrons will travel coming from the Wehnelt cathode will probably be many times greater than the distance that the electrons travel that originate with the tungsten filament.

There is one other point that seemed to me rather peculiar in connection with the experiment and that is the use of argon. Blue glow or glow of any kind in a gas is very different for different gases. If you take for example an electric discharge in neon or in argon at the same current you get more light from neon than you do from argon. The reason for that is that although argon produces probably just as much light as neon does in a given electric discharge, it so happens that nearly all the energy lies in the ultra-violet part of the spectrum which is invisible to the eye.

Neon produces; nearly all the light that it produces is in the visible spectrum. Different gases are entirely different with regard to the effect that they have in producing visible light, and argon is one of the gases that produces relatively less light than any of the others. It produces very little light.

You cannot build an argon lamp but a neon lamp is an efficient source of light. Argon probably would not give one one-hundredth as much light as neon under similar conditions.

Q. 15. Can you have blue glow without ionization?

A. Ionization is not the cause of the blue glow. It is perfectly possible to have a discharge in which there is a great deal of light produced, a glow throughout the whole bulb without any appreciable ionization of the gas as such. Glow in the gas is due not to ionization but to excitations of the atoms. It is due to the impact of electrons against atoms and molecules by which the electrons in the atoms are not knocked out of the atom but are displaced to other possible positions in the atom, and when they return they emit light.

Blue glow does not necessarily run parallel with ionization. Certainly the intensity of light due to it does not run parallel with ionization or other characteristics of the discharge except in so far as the given gas and given conditions with a given voltage and vary the current.

In general the more current you get the more light, but I have seen cases where just the reverse is true. I have seen a discharge in nitrogen where by increasing the current you absolutely stop the luminosity. I have seen currents of amperes in a mercury arc where I have not been able to see light at all as compared with a gas where there was less ionization and many times more light. In different parts of the same discharge tube you may have very great ionization in one place and very little light, and very much smaller ionization in another place with a great deal of light.

Q. 16. I want to be sure about the identification. This is the tube which you have in your hand and of which you were speaking in your answer with reference to the blue glow test this morning.

A. Yes.

Q. 17. And that is Defendant's Exhibit No. 329?

A. Yes.

MR. DAVIS: Direct examination closed.

(After a short recess.)

MR. DARBY: We have no cross-examination, your Honor.

THE COURT: What further evidence have you, Mr. Davis?

MR. DAVIS: I have merely, if your Honor please, to express the thanks of myself and my associates, and counsel on the other side, for the very great patience and kindness you have shown during this trial.

THE COURT: I appreciate very much the expression of those sentiments, but I want also to express to counsel in this case particularly, probably more so than any other, my realization of the great patience that they have had with me, layman, entirely unfamiliar with the art, and if you will be good enough, both of you, when you prepare your briefs, to forget that I sat in this case, and that I am taking it up afresh, as if I had not had the benefit of this trial, I think I will be able to make greater progress than if you presume possibly that I had learned something during the trial. I shall then be that much ahead, if I have done so.

MR. HAIGHT: When does your Honor wish to fix a time for argument?

THE COURT: I assume probably two days is what you want. March 9th and 10th. We will adjourn court until tomorrow at nine o'clock.

(Whereupon at 5.30 P. M., on November 11, 1926, the taking of testimony was closed.)

APPENDIX TO PLAINTIFF'S RECORD.

[Note: Taken under Rule 46. *See Volume II, page 1227.*]

A. I think that the long question had a "whether" in it, so that it cannot be answered as a yes or no question. I will have to ask to have it read. I thought you asked whether one thing happened or another?

Mr. Davis: Please read the question, Mr. Stenographer.

(Question repeated as follows: "Is it or is it not true that Professor Wien is a very distinguished physicist who has won the Nobel Prize and who has done a great deal of work and published a great deal on electrons and their properties——")

The Witness: May I answer that?

Mr. Davis: If you will, Doctor.

The Witness: It is true.

(The stenographer repeated the further part of the question as follows: "That you met Dr. Wien at dinner in the spring of 1913, and that you then and there discussed with him that you and your associates at Schenectady had tubes which operated by pure electron discharge, substantially independent of positive ionization?")

Mr. Davis: Will you please answer that, Doctor, under the rule?

The Witness: That is true also.

(The stenographer then repeated the further part of the question as follows: "And if your answer to that question is 'yes,' then I will ask you whether or not Professor Wien on hearing that statement expressed astonishment or incredulity?")

THE COURT: That asks for a witness's conclusion, and the only question that I could conceive would be on the border line of admissibility would be the one which asks what he did when that disclosure was made.

By MR. DAVIS:

Q. 179. Will you please answer that question, Dr. Langmuir, and state what Dr. Wien did when that was explained to him?

A. He expressed the utmost incredulity.

MR. HAIGHT: I ask that be stricken out.

THE COURT: I am not going to do that, because it is under Rule 46, and it is out any way, but it seems to me, Mr. Davis, if you want anything to be stated at all under Rule 46, to stay in, and be of any value, I may be wrong on the main proposition, but the answer of the witness would have to embody facts and not a conclusion of the witness.

Q. 180. Please state facts, Dr. Langmuir, as to what he did, whether he sat quiet, or whether he did not sit quiet, and what he said, if he said anything?

A. In referring to my statements that we had obtained pure electron discharges in the very highest vacuum, he said: "Dass kann nicht sein"—"That can't be so," and then told me of the work that had been done in Germany by various physicists, which he believed, or he stated he believed, proved to him that in a perfect vacuum, or a nearly perfect vacuum, electron currents could not be obtained from hot cathodes.

MR. DAVIS: Now, that is all subject to the rule, as I understand it, absolutely.

MR. HAIGHT: I am not entirely sure how that should be handled. Does that actually appear in the record at that point under the rule?

THE COURT: It will not appear in the record.

Mr. Haight: It should not be separated and put out?

The Court: No, that should be separated. I thought you meant whether it should be spread at large somewhere in that form.

Mr. Haight: I have no objection to that. I do not want it to appear in the body of this testimony.

The Court: That should appear in an appendix to the record.

Mr. Haight: Yes, sir.

OPINION OF COURT
(Filed January 3, 1928)

IN THE DISTRICT COURT OF THE UNITED STATES,
FOR THE DISTRICT OF DELAWARE.

General Electric Company,
Plaintiff,
v.
The De Forest Radio Company
Defendant.

IN EQUITY.
Nos. 589 and 598.

These two suits of General Electric Company against De Forest Radio Company were tried together. In the first suit all the claims of patent No. 1,558,436, granted to Irving Langmuir, assignor to the plaintiff, October 20, 1925, for "electrical discharge apparatus and process of preparing and using the same" upon an application filed October 16, 1913, and renewed March 14, 1916, are in issue. It is known as the high vacuum tube patent. Infringement is conceded if the claims are valid. Validity is denied for want of invention and novelty and because of prior knowledge and use, for double patenting and upon the ground that Harold D. Arnold, not Langmuir, was the first inventor.

The specification, claims and testimony are so interwoven with scientific theories, more or less abstruse, that it is somewhat difficult to isolate and keep separate from the principles of physics involved Langmuir's conception and idea of means. Yet an analysis of the Langmuir device and its elements discloses that, apart from its functioning and results, it is nothing more nor less than a Fleming valve or De Forest audion, for example, in which a higher vacuum, maintainable during operation, exists. How much higher the vacuum must be to bring the tube within the patent is not definitely fixed in terms of pressure. The specification states merely that "the evacuation of the device should be preferably carried to a pressure as low as a few hundredths of a micron, or even lower, but no definite limits can be assigned". A micron is a pressure equal to a millionth of a meter or a thousandth of a millimeter of mercury. It corresponds to a barometer reading of that value. The normal barometer reading in the open air is about 760 millimeters. The justification for the failure to assign definite pressure limits is that the invention "comprises devices in which the electrical current is carried by negative charges called electrons, emanating from the cathode, independently of gaseous ionization"—a device in which the residual gases play no part in the operation. The results desired to be obtained are stability and reproducibility of operation and increase of power. The production of these results by the specified manner of functioning is dependent not on the degree of vacuum alone but upon four co-ordinating variables—geometry or relation of parts of the tube, temperature of cathode, voltage of anode and degree of vacuum. This fact makes it apparently unavoidable that the claims be functional in form. But they must, of course, be construed to cover the thing. Walker on Patents, § 183. Claim 26 is comparatively simple. It is:

> "A discharge device comprising a sealed off envelope and electrodes therein, the envelope being shaped and the electrodes located so that the energy of the discharge is delivered mainly upon one or more of the electrodes, the inner wall of the envelope and electrodes being so free from occluded gas and the pressure in the tube being sufficiently low, with respect to the spacing of the electrodes and the energy of the discharge, so that the device is capable of passing a sustained discharge

of one-tenth of a milliampere at forty volts, without developing any substantial positive ionization effects."

The Fleming and De Forest tubes are "discharge devices comprising a sealed off envelope and electrodes therein, the envelope being shaped and the electrodes located so that the energy of the discharge is delivered mainly upon one or more of the electrodes". The next clause of the claim—"the inner wall of the envelope and electrodes being so free from occluded gas and the pressure in the tube being sufficiently low, with respect to the spacing of the electrodes and the energy of the discharge"—has to do with the manner and degree of evacuation. Underlying this clause are these facts: The glass wall and the electrodes harbor large volumes of occluded gases. Heat is necessary to expel these gases so they may be removed by the pump. If not removed before the tube is sealed off the heat occurring during the operation of the tube expels them, destroying in large degree the vacuum. "The spacing of the electrodes"—one illustration of the geometry of the tube—is a factor because the permissible gas pressure in the tube increases with the proximity of the electrodes to each other. This varying relation is due to the fact that the opportunity for the electrons to collide with gas molecules varies with the length of the path the electrons have to travel. "The energy of the discharge" may be interpreted in terms of power which is the product of the current values and the voltage. The unit of current flow is the ampere or the current which flows at a pressure of one volt through a closed circuit having a resistance of one ohm. The power of a circuit having a pressure of one volt and a current of one ampere is one watt. The power output of the device of claim 26 is .004 of a watt or 4 milliwatts. An increase of energy means an increase in the number and velocity of the electrons passing from cathode to anode and consequently an increase in the number and effect of collisions of electrons with gas molecules. It follows, of course, that if the maximum voltage at which a given tube will function without ionization is increased ionization will occur and the tube fail to function in the manner specified in the patent. "Ionization", by which is meant the conversion of atoms or molecules into ions, is explained by the "Electron Theory". By this all atoms known to chemistry are deemed to be made up of a nucleus endowed with a permanent positive electrical charge around which one or more electrons, each of which has mass or weight and carries, or is, a natural unit of electricity, revolve at inconceivably great speeds in regular orbits in somewhat the same manner as that in which the planets of our solar system revolve about the sun. According to this hypothesis the chief difference between the chemical atoms lies in the number and arrangement of their electrons. Under normal conditions the electrons are maintained within their atoms and in their orbits by the attractive force of the positive nucleus which, electrically, exactly balances and neutralizes the negative charge of the electrons of the atom. Consequently every atom having its normal complement of electrons exhibits no electrical effects. If, however, by impact, or otherwise, an atom loses an electron and becomes an ion it is thrown out of electrical balance. The positively charged nucleus predominates and exhibits a unit positive charge. In thermionic tubes ions are created by the impact upon the gas atoms or molecules of some of the myriads of electrons constituting the current flowing from the hot cathode to the cold anode—the Edison Effect. See *Westinghouse Elec. & Mfg. Co. v. De Forest Radio Tel. & Tel. Co.*, 21 Fed. (2d) 918. To dislodge an electron from its atom the colliding electron must have sufficient momentum. The velocity required for this momentum is given to the electrons mainly by the pull or attractive force of the positively charged anode. The strength of the pull increases, other conditions being stable, with the anode voltage. For the gases with which we are here concerned 15 to 25 or 30 volts constitute the ionizing voltages.

When substantial numbers of atoms or molecules are being converted into positive ions by the electron stream the "ionization effects" forbidden by claim 26 occur. One effect of ionization is an increase in the current across the tube over the value it would have at the same voltage in the particular tube were the vacuum sufficiently high to prevent ionization. Such increase is due to two facts. First, the electrons, being negative charges of electricity, tend in the absence of a countervailing force, violently to repel one another and thus to diminish the number, and, so, the value of the current, passing to the anode. Positive ions in the field constitute a countervailing force and consequently expedite the flow of the electrons to the anode. Second, the positively charged ions are drawn with great force to the cathode, the negative electrode, bombard it and thus increase its temperature. As the electron emissivity of the cathode increases with its temperature the ion bombardment of the cathode serves to increase the supply of electrons and consequently the current passing to the anode. This bombardment is so severe that, if continued, it destroys the filamentary cathode. Another effect to which substantial ionization usually gives rise is a blue glow in the tube. This, as I understand it, is accounted for upon the hypothesis that as the electrons are shifted in the atom, by impact of the electrons, from one orbit to another at prodigious speeds they produce waves or vibrations in the ether which constitute light. The ultimate effect or result of ionization is an unstable, non-reproducible and, in a measure, non-controllable current. As it is necessary, in order to prevent the destruction of the cathode and obtain a stable current, to operate gassy tubes below ionization, their power output—the product of current and voltage—was limited. These constitute obvious defects.

These defects are not present in the tube of the patent. It operates without substantial ionization. When there is no substantial ionization the current increases and decreases in a fixed relation to the voltage of the anode unless and until the anode voltage is made sufficiently high to draw to the anode all the electrons emitted at the cathode. The electronic emissivity of a given cathode increases with its temperature. This fact is known as "Richardson's Law". When a voltage high enough to carry across the tube all the electrons emitted is reached a further increase of voltage, which has no power to increase the supply of electrons of which the current consists beyond the limit of emissivity imposed by the temperature of the cathode, produces, of course, substantially no change in current. The current that is thus substantially independent of the voltage is known as the saturation current. Operation of the tube above and below this critical voltage is spoken of as in the saturation region and below saturation respectively. If a tube is operating below saturation an increase of the electron supply by an increase of cathode temperature, but with no increase in voltage, produces no marked change in the current. Decreasing the electrons emitted by the cathode by decreasing the cathode temperature is likewise without effect upon the current, provided, of course, that the decrease in the supply of electrons is limited to the electrons emitted in excess of those pulled across the tube by the given voltage. The fact that if the anode voltage remains stable the current can not be increased by an increase of the cathode temperature, beyond that required to supply the electrons capable of being pulled across the tube at the given voltage is illustrated by the "flat top temperature curve" on the following graph:

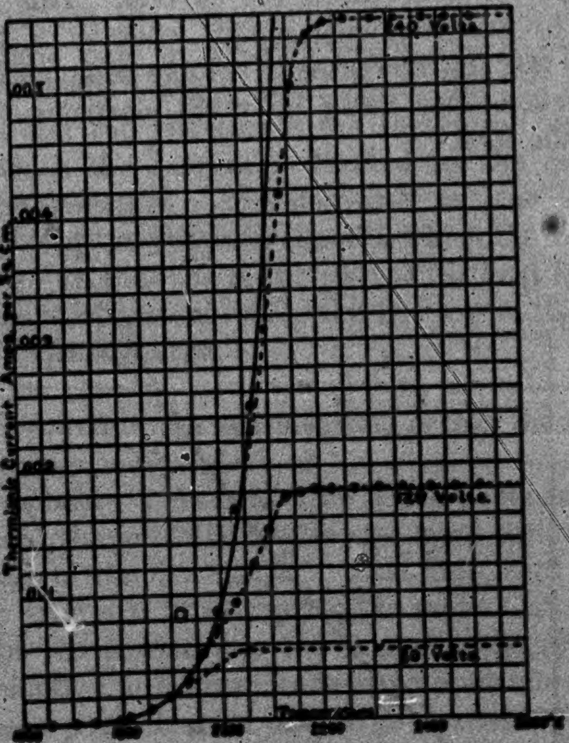

Fig. 1.

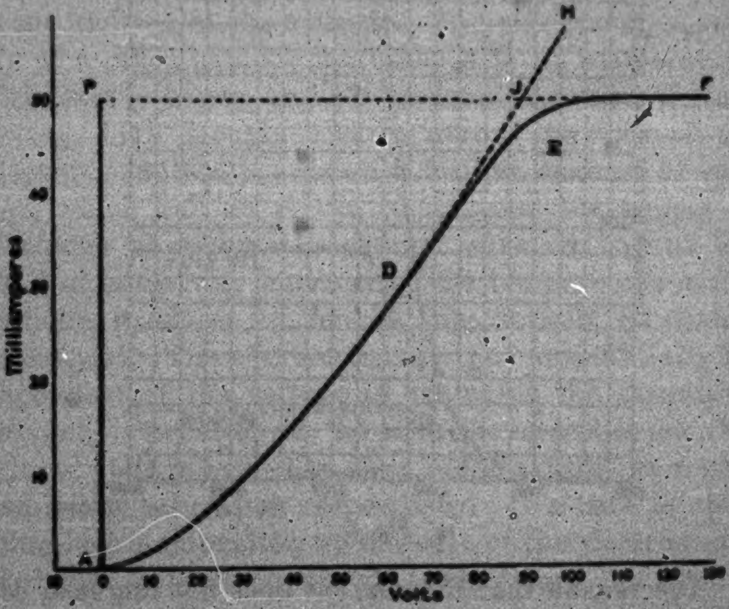
The reason that the current does not increase beyond a certain point dependent upon anode voltage with the increase of the temperature of the cathode is that the electrons, all being negatively charged, exert powerful repelling forces on one another. When this force of repulsion equalizes the pull or effect of the voltage on the anode, the anode is without power to draw to itself a greater number of electrons. The current-limiting effect of the electric field of the electrons on one another is known as the "space charge effect".

It is space charge which produces the flat top of the temperature emission curve in the foregoing graph.

When the temperature of a cathode is fixed and constant and the voltage is increased the limitation upon the electrons limits the current. This is illustrated by the following graph whereby it appears that the last few increases in voltage make no increase in current—there being no more electrons to draw across the tube.



The curve of this graph which when plotted on logarithmic paper appears, up to the point approaching saturation, as a straight line, discloses a relation existing between current and voltage. That relation is expressed in the specification thus:

> "In most devices of simple construction which embody my invention, the discharge current passing through a given space with the cathode at a sufficiently high temperature with respect to the

> voltages employed, varies directly with the 3/2 power [square root of the cube] of the impressed voltages."

"A" to "D" of the curve on the current-voltage chart, in which the temperature is constant, is the space charge part or that in which the current is limited by anode voltage and follows the 3/2 power law. The flat top represents the saturation part or that in which the current is limited by the cathode and its temperature. The converse is true in the first or current-temperature chart in which the voltage is constant. In that the rising part is the part limited by cathode temperature while the flat top is the part limited by space charge.

Another characteristic peculiar to the tube of the patent, as stated in the specification, is that the device is "practically independent of the pressure when the pressure is below a certain value which depends upon the size and shape of the device and upon the current and voltage of the discharge". That statement is undoubtedly true if it be interpreted to mean that if in a given tube the pressure is low enough to enable the tube to function at a given voltage without ionization, that is, as a pure electron discharge device, a further decrease in the pressure will not affect the discharge. It is likewise true that if the pressure is less than that required for a given voltage in a given tube it may be increased up to the pressure immediately below that at which substantial ionization would occur at the given voltage, without affecting the discharge. The discharge, however, is in no sense independent of the pressure if the maximum voltage at which a given tube will function without ionization is increased, for ionization would instantly occur and the tube fail to function in the manner specified in the patent. In such instance a decrease in pressure simultaneously with the increase in voltage would be necessary to avoid ionization. In its simplest aspect this is due, of course, to the fact that if ionization is to be avoided above ionization voltages collisions must be avoided between electrons and gas molecules and that the number of collisions in a given tube, dependent upon the relative density of the two, is increased, the pressure being stable, by an increase in the number of electrons pulled to the anode by the increased voltage.

These scientific explanations, arising mainly out of the electron theory, of the functioning of the high vacuum tube change not at all the fact that it differs structurally from the Fleming valve and De Forest audion only in the degree of vacuum maintainable during operation. This was expressly conceded during the pendency of the application in the Patent Office. The fundamental questions here in issue are not changed and their solutions are, I think, but little affected by the theories by which the functioning of the high vacuum tube is accounted for. If it was not known to those skilled in the art how to produce, in a Fleming or De Forest structure, for example, a vacuum sufficiently high to enable the tube to function above ionization voltages without substantial ionization and Langmuir solved the problem and made the necessary disclosure of its solution in his patent, manifestly he would be entitled to a patent for his disclosed method and device as a reward quite apart from his knowledge or lack of it with respect to scientific principles or laws of physics explaining the functioning brought about by the high vacuum. Moreover, independently of whether or not invention was necessary to create a vacuum of the required degree, Langmuir would be entitled, I take it, to a patent for his device regardless of his ability or inability to explain its functioning in principles of physics, if he was the first to appreciate that a high vacuum maintainable during operation in a Fleming or De Forest structure, for example, would constitute means whereby the results produced by the high vacuum tube could be accomplished, provided, of course, he reduced to practice with reasonable diligence the device of his mind.

Upon the question whether the claims for the process of making the high vacuum tube or those for the tube itself, which because of its stability, reproducibility and power has made possible radio broadcasting, modern radio reception and long distance telephony, involve novelty and invention the parties differ widely. The plaintiff asserts, with apparent confidence, that the patent is for invention of a high order —equal to or greater than that of De Forest for the three electrode tube. The defendant, with equal confidence, finds not only all that Langmuir did but all that he discloses with respect to the principles in accordance with which the device functions spread upon the records of the prior art. Since the Fleming valve and the De Forest audion were old and the structure of the tube of the patent differs from these only in the degree of vacuum maintainable during operation the first crucial question is whether claims 30, 31 and 32, directed to the process of making tubes having a vacuum of the required degree are valid. Claim 31 is:

> "In the process of producing a hot cathode discharge device, treating the interior surface of the envelope and the operating parts to liberate therefrom occluded gas, and removing from the envelope gas liberated by said treatment and free gas originally contained therein, continuing these operations until the occluded and original free gas is so thoroughly removed as to enable the finished sealed-off device to operate below saturation in a stable and reproducible manner at a voltage above fifty volts and with a current greater than one milliampere and with the energy of the discharge delivered mainly at one or more anodes."

To find wherein, if at all, this and the other process claims go beyond the discoveries and ideas of others, beyond the use of wise judgment in selecting and combining those discoveries and ideas, or beyond mechanical skill in applying them to practical results, the specification and the prior art must be examined. The specification states:

> "For the evacuation of the device the glass walls of the tube are carefully heated to as high a temperature as the glass will stand without softening and in general the most approved methods of incandescent lamp exhaust are used. The evacuation of the tube preferably while still heated is carried out by means of a suitable evacuating means, for example, a Gaede molecular pump, which removes vapors as well as gases. Chemical evacuating means such as electrically vaporized calcium or magnesium may also be used. Either before or during the evacuation the anodes may be heated especially when the anodes are to be run at elevated temperature during the normal operation of the device. In this case the temperature is preferably carried close to brilliant incandescence. In the case of the structure shown in Fig. 1, the heating may take place by passing an electrical current through the wire 12. The heating, especially of solid anodes such as shown in Figure 2, may take place in a suitable vacuum furnace, the temperature preferably being raised to 2,500° C. or even higher. Bombardment is a very effective means of removing occluded gas from anodes."

The steps and precautions requisite to successfully evacuate by bombardment are then described after which the specification adds:

> "After the metal has been freed from occluded gas reabsorption of gas will not readily take place even though it is exposed to the air or other gases. For example, anodes thus treated may be removed to other apparatus which then may be evacuated with less electron bombardment of the anode or

> anodes. . . . It is also true that when the anode has been carefully freed from gas, residual free gas, even if present in a sufficient amount to cause some gas ionization when the apparatus is first started, does little harm, as it is quickly removed by the gas clean-up effect when the device is operated."

The prior art, however, as I understand it, discloses that long before the earliest date claimed for Langmuir it was known not only that large quantities of gas are occluded in the glass walls and electrodes of an electrical discharge device and that unless removed before or during evacuation the gas will be driven out by the heat of operation and thus detrimentally increase the pressure of the vacuum, but also that the occluded gases could be removed and the vacuum created and maintained by the very steps prescribed by Langmuir for removing the occluded and free gases of his device. In May, 1896, the "American Electrician" published an article by Thomas Duncan in which he said:

> "If an incandescent lamp be exhausted until no air can be seen escaping through the valves of the pump, and the filament then incandesced, considerable quantities of air will be expelled at each operation of the pump, thereby showing that this air has been occluded in the pores of the carbon filament, and could not have been gotten rid of without heating the filament and driving the air out into the vacuous space surrounding it.
>
> "This heating also assists in drawing off the air which clings or adheres against the glass upon the inside of the bulb. . . . If the electrodes are made from aluminum or other porous metal, the secondary terminals from a spark coil can be applied to them, and set in operation in a similar manner to that in which the tube is to be used afterwards. This cannot help but be a ready and satisfactory means of eliminating the air occluded within the electrodes."

A résumé of Incandescent Electric Lamp Exhausting by S. E. Doane, published in the "Electrical World and Engineer" of May 21, 1904, says:

> "The exhausting of incandescent electric lamps has developed into a highly specialized branch of the lamp manufacture. . . . The completed lamp must not only be free from gases and vapors, but must also have had those parts capable of giving off gases and vapors, thoroughly freed from them. The only way we knew to accomplish this was to highly heat everything we wished to free from gas. We had three things to heat: the glass, the filaments and the joints between filaments and leading-in wires.
>
> "The glass was heated by an asbestos cone-shaped hood painted black on the inside. The heat from the lighted lamp furnished all the heat necessary. The lamps could be heated hot enough to cause the bulb to collapse if the hoods were made too thick. The filaments were also heated sufficiently by the current, . . ."

Dwyer, in his Patent No. 596,694, granted January 4, 1898, for a process of producing high vacuums in incandescent electric lamps or similar receptacles during their manufacture recites that in the past such lamps have been exhausted by mechanical pumps, "by chemical processes involving the displacement or absorption of the gases contained in the lamp, or by combinations of these processes". He says that a partial vacuum is readily obtained by a good mechanical or mercurial pump but that complete exhaustion by this means alone is not possible. He then adds:

> "To carry the vacuum still higher, it has been a common practice to heat the lamp-bulb by either an external source of heat, such as a gas-flame, or by an electric current passed through the lamp-filament, or by both of these means combined, so as to expand the gases in the lamp, and also to

> drive off from the lamp-filament itself and its supports, more particularly the joint between the leading-in wires and the filament, which joint is usually made of some form of hydrocarbon paste, gases occluded therein, while continuing the pumping operation."

Soddy, in his Patent No. 859,021 of July 2, 1907, for the employment of certain reagents in the process of producing high vacuum, declares:

> "In the production of high vacua not only has the air to be removed but also the gases occluded or condensed on the walls of the vessel being exhausted and on the contained electrodes or filaments or other contents of the said vessel, which condensed gases are given up slowly after exhaustion and if not removed during the exhaustion cause the vacuum to deteriorate. . . .
>
> "The heating and expelling of the condensed and occluded gases may be effected in any usual, or suitable, manner of expelling condensed or occluded gases from the walls and contents of vessels being exhausted. The usual manner of effecting such an operation is to heat the vessel while it and its contents are subjected to the same treatment as they are subjected to in after use. In incandescent electric lamps for example an electric current is passed through the filament, and in X-ray bulbs an electric discharge is passed between the electrodes during the continuation of the exhaustion."

Many other references disclose the baking of the walls of the envelope of a discharge device, the heating of the electrodes, incandescing the filament and electron bombardment of metallic electrodes to expel occluded gases. The gas clean-up effect was likewise old at the time Langmuir began his operations. One instance of its disclosure is in patent to Thatcher No. 1,028,636, granted June 4, 1912, application for which was filed March 30, 1910, for method of exhausting vessels, in which it is said in part:

> "I institute the intensive incandescence of the filament proper, that is I bring the current voltage up to a sufficient intensity to produce the blue haze phenomenon, and maintain the same until the blue haze disappears and the desired almost perfect vacuum is attained, . . . "

Dr. E. Leon Chaffee testified (R., Vol. 1, p. 159):

> "It has long been known that the existence of this blue glow improves the vacuum, probably by bombarding the walls with gas ions and consequently causing them to stick to the glass walls. . . . "

These steps of the prior art are the identical steps disclosed by Langmuir. Nor are his disclosures with respect to how these steps are to be employed any more ample or complete with the possible exception of heating by bombardment. But bombardment has no saving power for the claims are not restricted to heating by bombardment. They are broad enough to include any method of "treating the interior surface of the envelope and the operating parts to liberate therefrom occluded gas, and removing from the envelope gas liberated by said treatment and free gas originally contained therein". The plaintiff, however, places some reliance upon the clause in the claims directing continuance of the steps until the desired vacuum is attained and cites *Badische v. Kalle*, 104 Fed. 802. But in that case those skilled in the art were of the opinion that a more prolonged or intense application of the old steps would not accomplish the desired result. Such is not the evidence here as I understand it. Moreover, the tools of the evacuating art were constantly improving. In the early days of the incandescent lamp art manufacturers used the Sprengle pump to obtain their vacua. It gave way to the Geissler pump which, in its turn was superseded or supplemented by chemical evacuating processes. It is, I think, not denied that these old pumps and at least some of the chemical processes left in the tube mercury or other vapors having a pressure too high for the tube of the patent. But if Langmuir makes in his specification any disclosure of steps or means to avoid that result it is by the use of the new, improved Gaede molecular pump. That pump is highly efficient and, when properly used, leaves no free gas or vapor that will prevent the functioning of a thermionic tube above ionization voltages without substantial ionization. But Langmuir is entitled to no credit for that. I think the process claims are invalid.

This conclusion carries with it as a necessary corollary that the device itself, apart from its functioning and use, is lacking in patentable novelty. The inventive quality of the device claims, if any they have, must consequently reside in the discovery of a new principle that thermionic discharges above ionization voltages can be produced without substantial ionization if the vacuum be sufficiently high and the disclosure that the device of the claims constitutes suitable means for putting the principle into practice to obtain useful results, or, in the application of that principle, if known, to a useful purpose—in the realization that the instability, non-reproductibility and lower power output of the gassy tube was due to inadequate vacuum and the conception of a tube with a higher vacuum as a means whereby stability, reproductibility and high power output in thermionic devices might be had. That Langmuir was not the first to discover that a pure electron discharge, a discharge without substantial ionization, can be produced in a thermionic device if the vacuum is sufficiently high was indicated by Richardson's Law, evolved and formulated about 1903. If, perchance, that law was not universally accepted by physicists as being operative in high vacua, as was suggested by Soddy, Pring, Parker and some others, the publications of

Lilienfeld in 1910 were clear, complete and specific upon this point. In fact, Langmuir admits (I. R., p. 1378) that Lilienfeld had thermionic discharges above ionization voltages "substantially free from the effects of positive ionization". Moreover, if a thermionic discharge is unaccompanied by substantial ionization all the asserted "earmarks" or characteristics of plaintiff's device are present for they are but incidents flowing from a sufficiently high vacuum for the voltages employed, or, otherwise expressed, from an absence of ionization. These characteristics are, or include, (1) regularity and reproductibility of operation, (2) 3/2 power relation of current to voltage, (3) no blue glow or other visible evidence of discharge, (4) cathode not heated by the discharge, (5) current limited by space-charge effect, and (6) discharge independent of pressure in vacuum below certain pressure in the sense hereinbefore stated. As I understand the evidence these "earmarks" are likewise characteristics of the Fleming valve and original De Forest audion when operated at non-ionizing voltages. It thus seems obvious that the merit of the invention, if any, must lie in the realization that the known pure electron discharge to be had in a high vacuum would overcome the special difficulties and limitations of thermionic discharge devices. Whether this realization and the increase of vacuum in structures of the Fleming and De Forest type was a probable natural development of the art or one requiring inventive skill is, like the question of the presence or absence of invention in other cases, not without some difficulty.

One class of evidence which often carries much weight is the necessity for a series of experiments before the result can be arrived at. Such evidence raises a strong inference that the result was not obvious and constitutes a real addition to public knowledge. But for such experiments to be of much value the patentee must have started his experiments with knowledge of the state of the art or his experiments may have succeeded in enabling him to redisclose only what was already known. Langmuir made many experiments over a long period of time. Those that were first made were, however, for the purpose of discovering abstract principles and not for the purpose of arriving at practical results. He made discoveries but he did not immediately, or for some time, perceive that they had any practical use. Moreover, the discoveries to which his experiments led him, so far as we are here concerned, were those already made by Lilienfeld and others. Great credit, bearing upon the issue of invention, is claimed by the plaintiff for Langmuir for discovering from his experiments that electrons will boil out of a hot cathode in a high vacuum, that in a high vacuum the current varies with the 3/2 power of the voltage and other characteristics or incidents of a discharge in a high vacuum without substantial ionization. But disclosures of the prior art reveal that Langmuir, great and renowned physicist that he is justly conceded to be, was, in this instance, traveling all unknown to him, over a field already well explored. Fleming, the inventor of the Fleming valve, published in the "Scientific American Supplement" for January 20, 1906, an article on the electric conductivity of a vacuum, disclosing not only that electrons are emitted by a hot cathode in a high vacuum but also "that a high vacuum may be a very good conductor, provided that the negative electrode is rendered incandescent. This shows that the obstruction which a high vacuum offers to the passage of electricity is not due to the mere reduction of the matter in the space (that is, to the rarefaction of the gas), but is, in some way or other, largely dependent upon the temperature of the electrodes; the resistance to the passage of electricity through a vacuum can be rendered very small by intensely heating the negative electrode", thus revealing that a current could be had passing from cathode to anode. In addition, Fleming stated: "If we take measurements of the current passing through the vacuum when the negative electrode is an incandescent carbon filament and the other a cold metal plate, and, at the same time, measure the difference of potential between the electrodes, we find that the conductivity, as measured by the ratio of current to voltage, is not constant, but varies with the electromotive force." Furthermore, that Fleming knew the difference between a high and low vacuum is made manifest by his statement: "The vacuum is said to be low when the original normal air pressure in it is reduced to one-thousandth atmosphere, or it may be only to one three-hundreth. It is said to be high when it is reduced to one hundred-millionth of an atmosphere." It is true, as shown by the Fleming curve sheet, that Fleming did not employ in his valve a high vacuum but it is also true that Langmuir, Q. 212, conceded "There is no advantage in the device of the character of the Fleming valve to go to pressures of less than 50 microns". Both C. D. Child, in an article in the "Physical Review", Vol. 32 (1911), and Lilienfeld, in an article entitled "Conduction of Electricity in Extreme Vacuum", published in "Annalen der Physik", Vol. 32, (1910), disclosed that with the aid of certain simplifying assumptions, such as the ignoring of the initial velocity with which the electrons are boiled out of the cathode, the discharge current varies in accordance with the three-half power of the voltage. This is conclusive evidence, as I understand it, that in a high vacuum the current is under control, stable and reproducible and, since high voltages were employed, that high power levels may be attained by the employment of a high vacuum. "Space charge effect" was, likewise, but a rediscovery. This is made certain by an article by Lilienfeld in "Physikalische

Zeitschrift", 1908, in reply to an article by Soddy dealing with the Wehnelt cathode in high vacuum in which Lilienfeld said:

> ". . . it is not exclusively the electrons emitted from the oxide cathode which, as was often assumed, determined the discharge in high vacua, but that the discharge depends essentially on a second factor. I pointed out more specifically in my second paper this view, that in consequence of the absence of the last traces of gas the number (volume density) of the negative electrons supplying the current becomes great in comparison with the number of gas molecules per unit volume, so that therefore the tendency exists for the formation of the greatest possible negative space charge—which opposes the current transport by the negative electrons.
>
> "The higher the vacuum, the greater the current density, the more prominent this new kind of discharge becomes . . ."

That the discharge in high vacuum devices is practically independent of the pressure when the pressure is below a certain value was discovered by Langmuir after Lilienfeld had made the disclosure in his article of 1910, where he said:

> ". . . from a certain maximum value of the gas density downwards the number of positive charges formed per negative charge, *i. e.*, per negative electron is independent of the gas density.
>
> "Since we usually regard positive charges as originating from molecules (or atoms) we can put this result in the following form: the number of positive charges per molecule increases continually with diminishing gas density in the region of validity of the function K which is independent of the gas density provided other conditions (the potential gradient) are kept constant."

In view of these publications it seems to me that the only permissible inference to be drawn from Langmuir's experiments is not that they constitute evidence of invention but is rather that Langmuir was not abreast of the developments in this particular art when he made his experiments.

Other evidence bearing upon the issue of invention is the great utility of the high vacuum tube. But in 1912 the radio art was young. Fleming did not need for his purposes, as Langmuir testified, a higher vacuum than that employed by him. The De Forest audion was not in wide use. Langmuir did not see one until 1913. Under such circumstances it would be difficult to say that the high vacuum tube satisfied a long felt want or produced results long sought or that the evidence of utility is here indicative of anything more than a proper natural development of the art. Moreover, the fact that falls but little short of a demonstration that the employment of the known pure electron discharge above ionization voltages in tubes of the De Forest type was but the availment of those skilled in the art of the store of knowledge that had been accumulated and lay ready at hand is that when Arnold, who had had long experience with electrical discharges in high vacuum, was shown a De Forest audion for the first time on November 1, 1912, and saw it in operation he immediately realized and said, in effect, that by increasing the vacuum the discharge would be sufficiently stable and at adequate power levels to enable the tube to be employed as a relay device in trans-continental telephony. While not unmindful that invention may sometimes be the result of an instantaneous happy thought, yet the state of the art is strongly confirmative of Arnold's own view at the time that the improvement suggested by him was obvious to one skilled in the art. The act of Arnold turns the scale so overwhelmingly that it lies athwart a finding of invention.

The patent is likewise invalid, in my opinion, because of prior knowledge and use by De Forest. The specification states: "Ordinarily the gas ionization in the audion begins to be important somewhere between 20 and 30 volts." That, as I understand it, means that at this voltage the current becomes affected by positive ionization and the tube ceases to function as a pure electron discharge device. Yet, prior to August, 1912, the Federal Telegraph Company of California, by which De Forest was then employed, used a B battery of 36 cells, another of 45 cells, or 54 and 67½ volts respectively, with the audion. When used as an amplifier the amplification increases with the voltage. The testimony of Langmuir, x-Qs. 761-767, as I understand it, makes it clear that this voltage was employed for amplifying purposes and so with a discharge current substantially unaffected by ionization. That De Forest though not skilled in the art of evacuating his device, knew the effect thereon of an increased vacuum, though he was very probably unaware of the extent to which it could be carried, is disclosed by his letters of July 26, 1912, and August 14, 1912, to the McCandless Company, the manufacturer of audions for the Federal Telegraph Company. The first letter is:

> "Out of the last lot of 24 audion bulbs which you manufactured for us there are only 4 that came up to proper sensitiveness test. Apparently the vacuum in the other bulbs is too low, because in these latter bulbs we notice that the blue arc or cathode beam starts suddenly at 15 or 20 volts, under which condition the bulb is not sensitive."

The other letter reads:

> "We took two of the poorest of the discarded 20 to a San Francisco glass-blower, unknown to fame, and had him exhaust same to as high a vacuum as his pumps would take. These re-exhausted bulbs now show a sensitiveness equal to those of the first four which proves exclusively

> that our contention is correct. For the work which we demand from these bulbs they are not sufficiently sensitive and we would be glad therefore if you will re-exhaust them. You certainly should be able to put them in as good condition as the aforesaid San Francisco glass-blower."

The testimony discloses that the glass-blower referred to heated the tubes under an asbestos hood almost to the collapsing point of the tube while they were being exhausted. The references of the prior art which reveal that a lamp may be made to collapse by heating under an asbestos hood leave no room to doubt this testimony. Such heat was sufficient to heat to a certain degree the metal electrodes as well as the walls of the tube, thereby driving off from the electrodes as well as the walls some of the gasses occluded therein. The energy of the discharge of the De Forest tube was low. The bombardment was probably not adequate to heat the anode to a temperature even approximating that to which it was raised by the Bunsen burner under the asbestos hood. Consequently, little, if any, occluded gas would escape from the anode and the gas clean-up effect probably tended to improve the vacuum more that it was caused to deteriorate by the molecules of gas that escaped from the anode. The tubes were thus enabled to function substantially above ionization voltages without substantial ionization.

Upon the issue of priority, too, I think the plaintiff must fail. In the contest in the Patent Office between Arnold and Langmuir upon this issue the Examiner of Interferences awarded priority to Langmuir. The Examiners-in-Chief arrived at the same conclusion but for reasons conflicting with those of the Examiner of Interferences. The Commissioner of Patents awarded priority to Arnold. The Court of Appeals of the District of Columbia decided in favor of Langmuir for the reasons stated by the Examiner of Interferences and the Board of Examiners-in-Chief. I am in accord with neither of the divergent views expressed by the Examiner of Interferences and the Board of Examiners-in-Chief but, generally, with the reasoning and conclusion of the Commissioner of Patents. The defendant asserts that Arnold is entitled to the date of November 1, 1912. Upon that date Arnold, who because of his training and experience in the matter of electrical discharges in vacuum and upon recommendation of Dr. Robert A. Millikan, had been theretofore employed by Western Electric Company to aid in making possible trans-continental telephone service at the opening of the San Francisco Exposition, was shown by Doctors Jewett and Colpitts a De Forest tube that had been brought by De Forest to the Western Electric Company a day or so before. Arnold examined the audion and tested its performance as a repeater of speech currents. It functioned well with weak currents but choked, distorted the speech and blue hazed when increased plate voltage or loud speech currents were applied. Though Arnold had been engaged in perfecting a different device of his own to be employed for telephone relay purposes, he instantly saw that the performance of the tube which made it too unstable in its existing state for a telephone repeater was due to ionization and that this could be removed by increasing the vacuum. This he then disclosed to Colpitts and Jewett. He also understood and then explained to Colpitts that the hot cathode would emit electrons in the high vacuum, that they would be subject to the space charge effect and that it would require high plate potentials to obtain the desired electron flow from cathode to anode. Corroboration of the oral testimony of Arnold, Colpitts and Jewett, if needed, is to be found in the fact that every act of the Telephone Company from that time on is consistent only with the intended use of the audion made more rugged and with a higher vacuum in its trans-continental service. Arnold's conception of the invention, consisting in the full performance of the mental part of the inventive act, was complete. Nothing remained to be done but to give the device practical embodiment with reasonable diligence. If, in view of the fact that those skilled in the evacuating art knew how to reduce to physical form Arnold's mental conception, a physical reduction of his conception to practice was necessary, and I think it was not, *McCormick Harvester Mach. Co. v. Minneapolis Harvester Works*, 42 Fed. 152, 155; *Otto v. Linford*, 46 L. T. (N. S.) 35, this requirement was performed by Arnold with reasonable diligence, thus giving to him an effective date of November 1, 1912. He obtained, knowingly, in that month with audion 7-A a current of 3 milliamperes at 80 volts without substantial ionization. Again, Arnold met the requirements of reduction to practice in April and May of 1913. In the tubes of these experiments 250 volts were impressed upon the plate without ionization effect. The tubes used in Philadelphia in the fall of 1913 functioned well for many hours, one as long as 267 hours as commercial repeaters. The fact that the output energy of one of these tubes was less than that of the usual, original De Forest tube does not negative its being a tube of the patent, for the output energy of claim 26 is likewise less than the output energy of the usual, old De Forest tube. Moreover, it seems to me that other claims of the patent, for example 11, which was an original claim, differs from 26 in the same way and only in the same way that claim 26 differs from the original De Forest device.

Langmuir began his experiments in August of 1912. He now asserts and the defendant denies that he then obtained a pure electron discharge substantially unaffected by positive ionization but concedes, XQ. 380, that though he now knows that he did then obtain such a discharge he did not know it then. This lack of contemporaneous knowledge denies to his August work any effective value upon the issue of priority. Robinson on Patents, sec. 79, p. 121. In November Langmuir made other experiments but these he concedes were for the purpose of ascertaining the accuracy and existence of certain laws of physics. I find no evidence that he then thought of applying the scientific principles in which he was interested to any practical result in the useful arts. Consequently, there is no satisfactory evidence that Langmuir had a conception of the device of the patent before the end of November. "It is not while the creative energies are at work shaping and sharpening the idea of means that the conception of the invention becomes perfect. It is when these energies have ceased to act, when the idea stands before the mental vision of the inventor as clearly as a concrete invention before the eyes of an observer, that the conception is complete and the work of reduction is ready to begin." Robinson on Patents, sec. 379. Tested by this rule even the statements of Langmuir to Coolidge in December, 1912, did not reveal a complete idea of means and, consequently, did not disclose a complete conception within the meaning of the patent law. It was not until March 21, 1913, as I read the record, that Langmuir's conception or idea of means to a useful end began to take shape. He then made a record of it in these words: "Now, what I intend to do is to construct an audion which will operate entirely and exclusively on the electron discharge. I shall attempt to get the vacuum so good that positive ions are present in negligible amounts." It is not necessary to inquire when the conception became complete and his idea reduced to practice for Arnold had had the conception long before and had proceeded diligently to reduce it to practice.

The bill of complaint in this case must be dismissed.

In the second of the two suits between the same parties, tried together, three patents are involved. The first is No. 1,244,216 granted to Irving Langmuir, assignor to the plaintiff, October 23, 1917, upon an application filed July 15, 1914. In the record this is called the second patent, that for the high vacuum tube being referred to as the first. It is likewise known as the thoriated tungsten cathode patent. The specification states:

> "The present invention relates to electrical devices operating with a pure electron discharge and comprises a novel cathode material and the method of its preparation."

It recites that various refractory metals—platinum, carbon, tungsten, molybdenum—have been used as cathode materials and then announces:

> "I have discovered that the electron emissivity of pure thorium is of an entirely different order of magnitude than the emissivity of refractory materials heretofore used in electron discharge devices. It is not necessary that the electrode should consist entirely of thorium. When, for example, a thorium compound, such as the oxid, has been added during the process of production to one of the highly refractory metals, for example tungsten, and the metal subjected to a preliminary heat treatment in a high vacuum, the electron emission in a high vacuum is enormously increased."

The method of obtaining the high vacuum enabling the device to operate with a pure electron discharge is stated thus:

> "The preliminary evacuation of the envelope is carried out by the usual methods of producing high vacuum, which includes baking out the envelope to remove water vapor. The final state of

the evacuation is preferably but not necessarily carried out by a Gaede molecular pump to the highest possible vacuum obtainable by this means, —that is, to about .001 micron. While the apparatus is still on the pump the filaments 2, 3 are heated to a temperature of about 2900° K. (absolute) for a short time and the envelope 1 is baked out in an oven at a temperature of about 360 to 450° K. [C.]. The apparatus may then be sealed from the vacuum system at the contraction 10." (Incidentally this statement is strongly confirmative, it seems to me, of the conclusion arrived at with respect to the process claims of the first patent.)

Directions for aging follow. The disclosure that the vacuum may be increased by vaporizing one of the filaments is added. The economic and practical advantage arising from increased electron emissivity at the same temperature or an equal emissivity at a lower temperature is the lessened expense incident to the lessened energy required to heat the cathode. The claims in issue are 1 to 7 inclusive, 10 and 11. Claim 3 is:

> "A cathode for electron-discharge apparatus consisting largely of a highly refractory metal and a surface layer of material having an electron emissivity at a given temperature materially greater per unit surface than said refractory metal independently of and in the absence of positive ionization."

The "surface layer" element of the claim is based upon the fact or theory that by incandescing the filament some of the thoria therein is converted into metallic thorium which forms into a film or skin one atom thick on the surface of the cathod.

The pith of invention, if it exists, lies in the employment of a thoriated tungsten filament for the cathode in a high vacuum tube. That invention is to be found in any claim the defendant denies. This denial it rests primarily upon the ground that thoriated tungsten filaments were in general use in incandescent lamps for some time before the date of Langmuir's application and were gradually supplanting all other filaments. It asserts that, by reason of the analogy existing between the incandescent lamp and the radio tube it was both natural and obvious to use in the tube a filament the same as that employed in the lamp. It shows by evidence that since the origin of radio tubes filaments the same as those used in incandescent lamps had been employed in the tube—in fact, that it was not unusual actually to take filaments from lamps and put them in tubes. It points out that the preparation of filaments is the same for tube and lamp. It contends that it being natural and obvious to use in tubes filaments identical with those employed in lamps and it appearing that it was not unusual actually to transfer filaments from lamp to tube, the analogous user is not converted into a non-analogous use and invention by the discovery that a thoriated tungsten filament possesses greater electronic emissivity than the earlier filaments. It urges that the public should not be barred from reaping all the advantages and benefits incident to doing that which was the natural and obvious thing to do.

It is conceded that lamps with thoriated tungsten filaments were on the market as early as the fall of 1912 and that they gradually superseded lamps with other filaments. It is not denied that filaments identical with those employed in incandescent lamps were used in radio tubes. In fact the specification of the patent in suit states that platinum, tungsten and molybdenum, as well as carbon—lamp filament materials—had been used as cathode materials. The evidence is clear that it was not unusual in the manufacture and repair of De Forest audions to obtain cathode filaments directly from incandescent lamps. Indeed, the evidence indicates a strong probability that thoriated tungsten filaments were used in radio tubes before Langmuir's effective date although it lacks, I think, the degree of certainty required to sustain a finding of prior knowledge and use. Nor is the parallelism or identity of filament in lamp and tube surprising. Fleming, in patent No. 803,684 issued in 1905, employed for the original radio tube "a carbon filament like the carbon filament of an incandescent lamp." Each carries current, is heated in operation to a high temperature and so must not be readily fusible. It is true that the ultimate purpose of the current in the lamp filament is light and in the filament of the tube is electronic emission, yet these are not independent of each other as witness the Edison effect discovered in the lamp and the light visible in the radio tube. To be sure the different materials differ in their electronic emissivity. But this was pointed out at least as early as 1910, by Fleming in his patent No. 954,619. When the thoriated tungsten filament went into general use in the lamp art those skilled in the radio art knew with certainty that it had all the requirements for that art if it possessed the property of electronic emissivity to a satisfactory degree. The ascertainment of that fact called, I think, only for the routine work of those skilled in the art in the selection of the best among the materials known to be available. At most it required only the judgment and skill of the engineer and not the acumen and genius of the inventor. The question pertinent in all cases of this character—whether the new use lies so far out of the track of the former use as not naturally to suggest itself to a person skilled in the art turning his mind to the subject—must, consequently, I think, be answered in the negative.

The third patent of this record, No. 1,244,217, granted to Irving Langmuir, assignor to the plaintiff, October 23, 1917, upon an application filed October 28, 1915, relates to electrical devices having a thoriated cathode. The specification sets out that in the preparation of these devices "great care must be exercised to remove the last traces of oxygenous gases, particularly water vapor, and precautions must be observed not to evolve water vapor from the bulb walls during the operation of the device." The object or purpose of the invention is to improve the device and render its preparation easier "by providing in the envelop a quantity of a vaporizable reagent of low vapor pressure capable of preventing the oxidation of thorium." An alkali metal, for example, potassium, is preferred for this purpose but it is stated other reducing materials may be used. It is asserted in the specification that "The presence of the reducing agent in the main receptacle maintains the thorium reduced in spite of traces of water vapor which may be liberated from the glass. In an event the high electron emissivity of the thoriated cathode is more easily secured and maintained in the presence of the reducing agent than without it." The claims in issue are:

> "1. An electrical discharge device comprising electrodes, one of which contains thorium, an inclosing envelop the space within which is evacuated to a pressure so low that positive ionization is substantially absent, and a quantity of vaporizable reagent capable of preventing the oxidation of thorium in communication with the space within said envelop."
>
> "4. An electrical discharge device comprising electrodes, one of which consists of metallic tungsten and a thorium material in an oxidizable state, an inclosing envelop, and a quantity of a vaporizable reagent within said envelop capable of preventing the oxidation of thorium at an elevated temperature."

Conceding infringement if the claims are valid, the defendant denies validity upon the grounds of anticipation, non-invention, aggregation and double patenting.

Many exhibits evince the earlier knowledge that certain vaporizable reagents constitute means of obtaining—"getting" a vacuum of a high degree. As early as 1894 Malignani discovered, and disclosed in his patent No. 537,693, granted in 1895, this process for evacuating incandescent lamps. The reagent was put in a tubular elongation of the bulb and the bulb exhausted by pumping. The vacuum having been obtained, the lower end of the tube was soldered up and the carbon filament brought to intensive incandescence, to expel the gases contained therein. Simultaneously the part containing the vaporizable substance was heated by suitable means such as a spirit lamp to vaporize the chemical reagent. The vapors so generated combine with the free gas and vapors of the tube and those expelled from the filament and form a solid or liquid precipitation, "so that an almost perfect vacuum is obtained." Arsenic and iodine were the reagents employed by Malignani. Dwyer also in patent No. 595,695, granted in 1898, made use of a chemical "having the property of evolving a condensable gas or vapor which, when the heating is discontinued, goes down as a solid upon the cooler portions of the receptacle and requiring quite a high temperature to be afterward again vaporized." Dwyer limited the amount of the chemical so as to have the least possible amount of foreign substance deposited as a film upon the inner surface of the lamp bulb. Doane, R., Vol. V, p. 138, describes the employment of phosphorus as a chemical exhausting means or aid. Merritt, patent No. 909,811, granted in 1909, after reciting the earlier use of suitable substance to act upon the deleterious gases, particularly oxygen, remaining in the bulb after pumping, and to convert them into harmless compounds shows the advantages to be had from putting the chemical in the bulb instead of in the tubulature. He restricted, however, the amount so there would be no excess to discolor the bulb. Soddy, patent No. 859,021, issued in 1907, described the process of bringing a heated alkaline earth metal—particularly calcium—capable of absorbing gas into the presence of the rarefied atmosphere whereby the remaining gases were absorbed. His article in "Nature" of November 21, 1907, showed that by means of calcium a copious mirror deposit on the inner walls of the tube might be had. But he does not indicate that such a deposit is useful or desirable. Clark, in patent No. 1,121,802, issued in 1914, made use of vaporized sodium/or potassium to coat the inner wall of projector lamps with reflecting surfaces. He explained that since sodium and potassium oxidize very readily when in the presence of oxygen it is necessary to apply the coating with no trace of oxygen. Von Recklinghausen, in patent No. 946,068, applied for in 1904 and granted in 1910, made use of magnesium, in mercury vapor apparatus, for absorbing some of the gases which remain after a certain degree of exhaustion by pumping has been attained. He claimed "The combination with a closed container, of a holder within the container, magnesium within the holder, and a source of electric current connected with the opposite ends of the magnesium whereby the same may be rendered active for absorbing injurious gases in the container."

An analysis of these and other disclosures of the prior art shows, however, that they all fall short of the underlying idea of the third patent. They reveal that chemical agents had become a most potent aid to the pump in creating—"getting"—vacua of the required degree. But nowhere is it indicated that the reagent has any practical value after the moment of volatilization—after it becomes cold—and nowhere is there a suggestion that by retaining the volatilized reagent within the sealed off bulb the vacuum obtained may be maintained. In short, the prior art discloses the use of chemicals as "getters." It does not disclose their use as "keepers." Langmuir made a step forward. He grasped the fact that by retaining the reagent within the tube it would continue to function after the moment of volatilization even though cold and so combine with and form into a harmless solid compound any molecules of free gas, particularly oxygen, that might evade the evacuation process and any molecules of occluded gas that might escape from walls or electrodes during operation of the tube. By this means the efficiency of the readily oxidizable thoriated cathode is preserved and its life prolonged. It is a true combination—not an aggregation.

Patent No. 1,159,307, applied for March 20, 1914, and granted November 2, 1915, to William C. White, assignor to the plaintiff herein, upon which defendant herein relies to show invalidity of the claims of the third Langmuir patent here in issue on the ground of double patenting is for a different purpose. The vaporizable substance retained in the tube by White is of a character to maintain the gas in the tube at the definite pressure at which the device possesses a critical region of sensitiveness. That retained by Langmuir, within the meaning of the claims, is of a character to capture and combine with the molecules of gas and maintain the vacuum. I think the claims in issue of the third patent are valid and infringed.

The fourth and last patent in suit is No. 1,529,597, applied for August 11, 1921, and granted March 10, 1925, to Irving Langmuir, assignor to the plaintiff herein. Like the third patent it has to do with "keepers." The advance marked by it is in the employment for that purpose of an alkaline earth metal, preferably magnesium, instead of potassium or other alkaline metals suggested in the third patent. The claims in issue are 12, 13, 18, 19, 21, and 22. Claim 13 is:

> "An electrical discharge device comprising a sealed envelope, electrodes therein one of which is of the thoriated type and a film of magnesium deposited on the inner surface of said envelope."

The claim to invention rests upon the discovery of special advantages incident to the use of magnesium. One advantage is set out in the specification thus:

> "A thoriated cathode may be deleteriously affected by positive ion bombardment, that is, when voltages materially higher than the ionization voltages are impressed between a thoriated cathode and a positive electrode in the presence of ionizable gas, then the beneficial effect of the thorium may be largely or entirely destroyed by positive ion bombardment. Although the alkali metals are entirely satisfactory as agents to remove deleterious gases when the operating temperature of the bulb is only moderately above room temperature, as in the case of radio receiving tubes, these alkali metals have a sufficiently high vapor pressure at the operating temperature of power devices in which cathodes of the thoriated type are used to become ionized at higher voltages and to cause removal of the active film of thorium from the cathode by bombardment. I have found that it is advantageous in many cases to provide a device containing a cathode of the thoriated type, with a material having an affinity for gases, such as magnesium, for example, which at the operating temperature of the device, has substantially no vapor pressure. . . . "

Another advantage lies in the avoidance of the danger incident to the use of potassium which is so oxidizable that it must be kept under oil for it breaks into flame when exposed to the air. Magnesium is handled without difficulty. Obtained in the form of wire or foil it can be cut up in the open air and fed to the machines without danger.

The broad question here presented is, of course, whether making the keeper element, of the old device, of magnesium instead of some other material, particularly an alkali metal, involved invention. As I understand the law there may be invention in selecting a particular material for a particular purpose although other materials of the same class have been used before for the same purpose and even though a patent has been previously granted for the use of the whole class. *Potts v. Creager*, 155 U. S. 609; *Andrew's Patent*, 25 R. P. C. 477. But courts which scrutinize such patents somewhat narrowly require, before invention may be found, that it must at least appear not only that there is a special advantage attached to the use of the particular substance claimed but also that its use is not the mere substitution of a superior material for an inferior, is not the result of judgment and skill in the selection of materials, nor a probable consequence of the natural development of the art. That magnesium has an affinity for gases, particularly oxygen, has long been well known. The availability of magnesium as a "getter" because of that property, was disclosed by Von Recklinghausen in patent No. 946,068, by British patent No. 15,788 of 1914 granted to the British Thomson-Houston Company, Limited, as a result of a communication from the plaintiff herein, and by Mackey in patent No. 1,208,597. Soddy, in patent No. 859,021, made use of alkaline earth metals, preferably calcium, which is suggested by the patent in suit as an equivalent for magnesium, to absorb the residual gases of a vacuum not sufficiently high.

It is of course true that magnesium, though highly oxidizable, does not oxidize so readily as potassium, yet in view of its known efficiency as a "getter" I find nothing in the record to indicate that its use as a "keeper" involved more than judgment and skill in the selection of materials by those conversant with the art.

The language of claims 1 and 4 of the broad "keeper" patent and the known properties of the alkaline earth metals make it certain, I think, that those metals lie within the scope of those claims. Langmuir could not have been restricted in the exercise of the invention of those claims by a subsequent patent to another for the employment of the alkaline earth metals as keepers. Conversely, Langmuir can make no valid claim whose effect would be to extend the term of the monopoly that he obtained by the grant of the third patent. This makes inevitable a conclusion that the claims here in issue of the fourth patent are invalid.

Decrees in conformity herewith may be presented.

(Sgd.) HUGH M. MORRIS, *J.*

DECREE

(Filed January 16, 1928)

IN THE UNITED STATES DISTRICT COURT,
FOR THE DISTRICT OF DELAWARE.

General Electric Company v. *De Forest Radio Company.*	No. 589. IN EQUITY.

And now, to wit, this sixteenth day of January, 1928, this cause having come on to be tried and heard at this term and having been argued by counsel, and thereupon, upon consideration thereof, it is

ORDERED, ADJUDGED and DECREED by the Court, that the bill of complaint herein be and it hereby is dismissed for want of equity with costs to be taxed by the clerk in favor of defendant and against plaintiff.

(Sgd.) HUGH M. MORRIS,
U. S. Judge.

Form assented to.

(Sgd.) WM. G. MAHAFFY,
Solicitor for Plaintiff.

(Sgd.) HOWSON & HOWSON,
Counsel for Plaintiff.

PETITION FOR APPEAL

(Filed January 23, 1928)

IN THE UNITED STATES DISTRICT COURT,
FOR THE DISTRICT OF DELAWARE.

General Electric Company v. *De Forest Radio Company.*	No. 589. IN EQUITY.

The plaintiff, General Electric Company, conceiving itself aggrieved by the decree made and entered herein as of the sixteenth day of January, 1928, does hereby appeal from said decree to the United States Circuit Court of Appeals for the Third Circuit, for the reasons specified in the assignment of errors which is filed herewith, and it prays that this appeal may be allowed and a citation granted directed to the above-named defendant, De Forest Radio Company, commanding it to appear before the United States Circuit Court of Appeals for the Third Circuit, to do and receive what may appertain to justice to be done in the premises and that a transcript of record, proceedings and papers upon which said decree was made be duly authenticated and sent to the said United States Circuit Court of Appeals for the Third Circuit.

GENERAL ELECTRIC COMPANY,
By (Sgd.) WM. G. MAHAFFY,
(Sgd.) HOWSON AND HOWSON,
Solicitors for Plaintiff.

Dated January 23, 1928.

ORDER ALLOWING APPEAL

(Filed January 23, 1928)

IN THE UNITED STATES DISTRICT COURT,
FOR THE DISTRICT OF DELAWARE.

General Electric Company
v.
De Forest Radio Company.

No. 589.
IN EQUITY.

AND NOW, to wit, this twenty-third day of January, A. D. 1928 upon consideration of the annexed petition for appeal in the above cause, it is, upon motion of William G. Mahaffy, solicitor for the petitioner,

ORDERED BY THE COURT that the appeal of the said plaintiff prayed for therein be and is hereby allowed, and the amount of the appeal bond to be entered by appellant is hereby fixed at the sum of five hundred dollars ($500).

(Sgd.) HUGH M. MORRIS,
J.

ASSIGNMENT OF ERRORS

(Filed January 23, 1928)

IN THE UNITED STATES DISTRICT COURT,
FOR THE DISTRICT OF DELAWARE.

General Electric Company
v.
De Forest Radio Company.

No. 589.
IN EQUITY.

The plaintiff, General Electric Company, in the above-entitled suit, conceiving itself aggrieved by the decree entered in this suit on the sixteenth day of January, 1928, now appears by its counsel and presents with the accompanying petition for appeal from said decree the following assignment of errors:

First.—The trial Court erred in entering a decree dismissing the bill for want of equity.

Second.—The trial Court erred in not entering a decree for the plaintiff for injunction against, and for an accounting by, defendant, by reason of infringement of the Langmuir Patent No. 1,558,436.

Third.—The trial Court erred in holding said patent invalid.

Fourth.—The trial Court erred in holding the subject matter of said patent lacking in invention.

Fifth.—The trial Court erred in holding the subject matter of said patent to be lacking in patentable novelty.

Sixth.—The trial Court erred in holding the patent invalid because of prior knowledge and use by Lee De Forest.

Seventh.—The trial Court erred in holding that the subject matter of said patent was previously invented by Harold D. Arnold.

Eighth.—The trial Court erred in not holding said Langmuir Patent No. 1,558,436 valid and infringed by defendant as to all the claims thereof.

GENERAL ELECTRIC COMPANY,
By (Sgd.) WM. G. MAHAFFY,
(Sgd.) HOWSON AND HOWSON,
Its Solicitors.

January 23, 1928.

CITATION
(Filed January 30, 1928)

IN THE UNITED STATES DISTRICT COURT,
FOR THE DISTRICT OF DELAWARE.

General Electric Company v. *De Forest Radio Company.*	No. 589. IN EQUITY.

THE PRESIDENT OF THE UNITED STATES,

To the De Forest Radio Company,

GREETING:

You are hereby cited and admonished to be and appear in the United States Circuit Court of Appeals for the Third Circuit to be held in the City of Philadelphia, in the State of Pennsylvania, on the twenty-sixth day of February, 1928, pursuant to an appeal duly allowed and filed in the office of the clerk of the District Court of the United States for the District of Delaware, wherein General Electric Company is plaintiff-appellant, and you are defendant-appellee, to show cause, if any there be, why the decree in such appeal mentioned should not be corrected and speedy justice should not be done to the parties in that behalf.

Given under my hand in the City of Wilmington, in the District of Delaware, this 27th day of January, A. D. 1928, and of the independence of the United States the one hundred and fifty-second.

(Seal)

(Sgd.) HUGH M. MORRIS,
United States Judge.

Service of the within citation with copy accepted this 30th day of January, 1928.

(Sgd.) E. E. Berl,
Solicitor for Defendant.

STIPULATION AS TO TRANSCRIPT

(Filed March 8, 1928)

In the District Court of the United States,
For the District of Delaware.

General Electric Company v. *The De Forest Radio Company.*	No. 589. In Equity.

It is hereby stipulated and agreed by and between counsel for the respective parties, with respect to the transcript of record on the appeal taken by the plaintiff from the decree entered in the above-entitled cause and also the cross appeals in the cause between the same parties No. 598 in equity in this court, as follows:

1. That the two causes having been tried together in 1926, a single consolidated transcript of record for the appeals may be used in the United States Circuit Court of Appeals for the Third Circuit for the two causes, and such consolidated transcript of record having been printed early in 1927 in six volumes for the use and convenience of the District Court, without reduction of the testimony to narrative form, in the belief that such printed record could and would be available for use also in the United States Circuit Court of Appeals, it is stipulated that said six printed volumes shall constitute the transcript of record on said appeals when there shall have been added thereto the following

(a) Additional docket entries and new index,
(b) The opinion of the District Court,
(c) Decree,
(d) Plaintiff's petition for appeal, allowance of appeal, assignment of errors,

(e) This stipulation and order thereon, and
(f) Clerk's certificate.

2. That the three-volume record in the Interference Arnold v. Langmuir need not be reprinted, but may go up as a physical exhibit, in three copies.

3. That all exhibits not printed in the six volumes referred to in clause 1 hereof but listed therein, shall also go up as physical exhibits.

(Sgd.) WM. G. MAHAFFY,
Solicitor for Plaintiff.

(Sgd.) HOWSON AND HOWSON,
Counsel for the Plaintiff.

(Sgd.) E. E. BERL,
Solicitor for Defendant.

(Sgd.) SAMUEL E. DARBY, Jr.,
Counsel for the Defendant.

February 23, 1928.

ORDER APPROVING STIPULATION

(Filed March 8, 1928)

And Now, to wit, this eighth day of March, A. D. 1928, on motion of William G. Mahaffy, Esq., solicitor for plaintiff-appellant,

It Is Ordered by the Court that the foregoing stipulation be and hereby is approved and the clerk is hereby authorized to certify the transcript of record prepared in accordance therewith, and to transmit the same together with the physical exhibits referred to therein, to the United States Circuit Court of Appeals for the Third Circuit, at Philadelphia, Pennsylvania.

(Sgd.) HUGH M. MORRIS,
J.

DECREE.

(Filed January 16, 1928)

IN THE DISTRICT COURT OF THE UNITED STATES,
FOR THE DISTRICT OF DELAWARE.

General Electric Company
v.
The De Forest Radio Company.

No. 598.
IN EQUITY.

And now, to wit, this sixteenth day of January, 1928, this cause having come on to be tried and heard at this term, and having been argued by counsel, and thereupon, upon consideration thereof, it is

ORDERED, ADJUDGED AND DECREED by the Court that the bill of complaint herein be and it hereby is dismissed for want of equity as to the two Langmuir patents numbered 1,244,216 and 1,529,597, but as to those patents only;

That as to the Langmuir Patent No. 1,244,217 it is ORDERED, ADJUDGED and DECREED as follows:

1. That Letters Patent of the United States here in suit No. 1,244,217, dated October 23, 1917, to the plaintiff General Electric Company as assignee of Irving Langmuir, for electron discharge apparatus and method of operating the same, are good and valid in law as to claims 1 and 4 thereof;

2. That the plaintiff, General Electric Company, is the owner of said Letters Patent 1,244,217 and of all

rights therein and thereunder and has been such ever since the grant thereof;

3. That the defendant, The De Forest Radio Company, has infringed upon said claims 1 and 4 of said Patent 1,244,217 and the rights of the plaintiff therein and thereunder;

4. That a permanent injunction issue out of and under the seal of this Court directed to said defendant, its officers, employees, servants, attorneys, agents and privies, and each of them enjoining and restraining them and each of them from directly or indirectly infringing upon said claims 1 and 4 of said letters patent or either of them or contributing to the infringement of the same;

5. That the plaintiff do recover of the defendant all of the profits, gains and advantages which the defendant has derived, received or earned or made by reason of said infringement and the damages which the plaintiff has sustained by reason of said infringement, the account to be taken and stated and the damages to be assessed by proceedings appropriate for such purpose;

6. That the question of costs in this suit be reserved for the entry of final decree.

(Sgd.) HUGH M. MORRIS,
J.

PLAINTIFF'S PETITION FOR APPEAL

(Filed January 23, 1928)

IN THE DISTRICT COURT OF THE UNITED STATES,
FOR THE DISTRICT OF DELAWARE.

General Electric Company
v.
De Forest Radio Company.

No. 598.
IN EQUITY.

The plaintiff General Electric Company conceiving itself aggrieved by the decree made and entered into herein as of the sixteenth day of January, 1928, in so far and only in so far, as said decree relates to Patents No. 1,244,416 and No. 1,529,597, does hereby appeal from said decree so far as it relates to said two patents to the United States Circuit Court of Appeals for the Third Circuit for the reasons specified in the assignment of errors which is filed herewith, and it prays that this appeal may be allowed and a citation granted directed to the above-named defendant De Forest Radio Company, commanding it to appear before the United States Circuit Court of Appeals for the Third Circuit to do and receive what may appertain to justice to be done in the premises and that a transcript of record, proceedings and papers upon which said decree was made be duly authenticated and sent to the said United States Circuit Court of Appeals for the Third Circuit.

APPEAL FROM THE DISTRICT COURT OF THE UNITED STATES, FOR THE DISTRICT OF DELAWARE.

This cause came on to be heard on the transcript of record from the District Court of the United States, for the District of Delaware, and was argued by counsel.

On consideration whereof, it is now here ordered, adjudged, and decreed by this Court that the decree of the said District Court in this cause be, and the same is hereby affirmed, with costs.

Philadelphia, October 3, 1929.

(Sgd.) J. WARREN DAVIS,
Circuit Judge.

PETITION FOR REHEARING.

UNITED STATES CIRCUIT COURT OF APPEALS, FOR THE THIRD CIRCUIT.

March Term, 1928. Nos. 3799 and 3800.

General Electric Company
v.
DeForest Radio Company.

In asking the Court to reconsider this case we do so with full appreciation of the careful and patient attention accorded to counsel at the argument, and with sympathetic understanding of the Court's reluctance to grant a rehearing except upon a showing of material and palpable error. We are convinced that such an error has been made, and we conscientiously feel that unless opportunity is given to correct it, grave injustice will result, and a meritorious and highly useful invention denied the protection which the Constitution intended to afford.

1. THE INVENTION IN RELATION TO THE PRIOR ART.

What the invention is.

The invention is an improvement in radio tubes, specifically the Fleming valve and DeForest audion.

In a radio tube electric current flows through a metal conductor, such as copper wire, from the battery to the filament, then somehow flows across the gap between the filament and the plate and then flows through a metal conductor from the plate back to the battery, forming a complete electrical circuit. The particular thing with which we are concerned in this case is how the current flows across the gap between the filament and plate and what causes it to flow.

For many years the art believed that electric current at any reasonable voltage would flow only through a metallic or liquid conductor. Then came EDISON in 1884 with his great discovery of the "Edison effect," which was, that somehow electric current would flow in a vacuum tube across a gap from a heated filament to a cold plate or anode. This was a startling discovery because at first thought it appeared to be utterly inconsistent with the accepted belief that current would flow only through a conductor. But like all great discoveries it appeared simple enough when it was explained. The explanation was that there was enough gas in the tube to form a conductor, or as it was sometimes described, that there was a "column of conducting gas" which served as a conductor to carry the current across the gap from the filament to the plate.

FLEMING merely utilized the Edison effect in a vacuum tube with its column of conducting gas for the production of radio signals. This was his contribution to the art.

DEFOREST simply improved the Fleming valve by adding the grid. This was DeForest's contribution.

Both Fleming and DeForest depended on the conductivity of gas as the fundamental basis of the operation of their tubes. They and the art believed, and repeatedly stated, that this physical conductor, this column of conducting gas, was necessary if any current was to flow across the tube. The Edison effect still depended on gas.

Then came LANGMUIR with a discovery quite as startling as the Edison effect. He got rid of all the gas so that there was no longer any gas to serve as a conductor, and he discovered that by a proper arrangement of the electrodes the current could be made to flow from the filament to the plate *without a con-*

ductor of any kind, and moreover that this current would follow a fixed law with relation to the voltage as contrasted with the current in a gas tube which followed no fixed law but varied with the conductivity of the gas.

IN SIMPLE LANGUAGE, LANGMUIR'S INVENTION CONSISTED IN TAKING OUT THE CONDUCTOR WHICH WAS IN THE FLEMING VALVE AND THE DEFOREST AUDION AND PUTTING NOTHING IN ITS PLACE; HE DISPENSED WITH WHAT WAS REGARDED AS AN ESSENTIAL ELEMENT IN THE OPERATION OF THE TUBE AND BY DOING SO MADE A TUBE WHICH WORKED INFINITELY BETTER.

This idea that current could be made to flow through sheer space without any conductor was just as startling, we submit, and quite as novel, as Marconi's original conception that telegraph signals could be transmitted without wires.

It has been suggested that the difference between Langmuir and DeForest is a mere matter of the degree of vacuum in the tube. This statement, however, overlooks the essence of the invention. If all Langmuir did was to make a tube work with less gas, still depending upon the gas for a conductor, this would be a mere matter of degree, just as for example the substitution of a larger copper wire conductor for a smaller wire would be a mere change of degree lacking in patentability, even though better results were accomplished; but to substitute for a wire conductor sheer space would not be a matter of degree, and to substitute for a gas conductor sheer space is likewise not a matter of degree.

Recognition of Utility.

The remarkable utility of Langmuir's invention is sufficiently attested by the Court's statement that the thing which he invented *"because of its stability, reproducibility and power, has made possible radio broadcasting, modern radio reception and long distance telephony."*

We conceive it to be an axiom of patent law that a thing which revolutionizes an art, which makes possible that which before was impossible, is invention. Yet notwithstanding this demonstration of novelty and utility, the majority of the Court, adopting the opinion of the lower Court, has said it is not entitled to patent protection because it represents nothing more than an obvious and natural development of the art.

Not an obvious development of the Art.

There is nothing in the record to support this astounding conclusion. **THE IDEA THAT A FLEMING VALVE OR DEFOREST AUDION COULD BE IMPROVED BY INCREASING THE VACUUM TO THE POINT WHERE THERE WAS NO GAS TO ACT AS A CONDUCTOR, WAS OPPOSED TO ALL THE EXPERIENCE AND TEACHING OF THE ART.**

What the art knew or thought is abundantly evidenced by the contemporaneous statements of those most conversant with it. It knew, through experience, that a good audion should be neither too soft nor too hard; that the tube must be exhausted *but not too well exhausted,* otherwise it would not function. DeForest said that "if the exhausting process is carried too far, the audion loses its sensitiveness" (Reply brief, p. 9), and this was supposed to be, and was, due to the fact, as explained by him, that the conductivity of the audion was "due to the ionization of the residual gases" (Main brief, p. 13). As he put it *"The gas particles, rather than the particles of metal dust are the carriers"* (I. R. 1496). Even after Langmuir had made his disclosure in a paper read before the Radio Institute, DeForest still insisted that he was working on the wrong track (Main brief, p. 39).

Fleming said the same thing, over and over again, with respect to his "valve"; for example in the year 1908 he stated that his valve depended "on the unilateral conductivity of a mass of rarefied gas" (I. R., p. 1337). In 1910 he spoke of this gas as being ionized (I. R., p. 1343). In 1916, long after Langmuir's invention was known to the world and to Fleming, he spoke of the "ionized gas" in his valve as a "conductor" (Main brief, p. 77).

It is easy enough to argue now that if the trickiness and unreliability of the audion were due to gas, the obvious way to get rid of those undesirable qualities was to get rid of the gas. But in the view of the art the gas was the thing that made the tube work; if you got rid of the gas you destroyed the tube. It might be an obvious way to get rid of the trickiness, but in the view of the art it would have been very much like cutting out a man's tongue to cure him from stuttering.

Certainly it is not an obvious and natural development of an art to improve an existing device by eliminating the very thing which is supposed to be essential to its operation.

The District Court apparently labored under the mistaken idea that an audion improved as the vacuum improved, and from this false premise concluded that the obvious way to improve the audion was to improve the vacuum. But the audion did *not* improve as the vacuum improved; it functioned at a certain vacuum which had to be neither too low nor too high. *When the vacuum improved, the tube did not improve; it became useless.* The transition from an audion to a high vacuum tube is not a gradual evolution; it is the creation of an entirely new and different thing.

Prior Art References.

We cannot but feel that the Court has unconsciously appraised the knowledge of the prior art in the light of Langmuir's work, and doing so has assumed that what now appears perfectly obvious, must have been so at the time. But as the Supreme Court has said:

> "Knowledge after the event is always easy, and problems once solved present no difficulties, indeed may be represented as never having had any, and expert witnesses may be brought forward to show that the new thing which seemed to have eluded the search of the world was always ready at hand and easy to be seen by a merely skillful attention. But the law has other tests of the invention than subtle conjectures of what might have been seen and yet was not. *It regards a change as evidence of novelty, the acceptance and utility of change as a further evidence, even as demonstration.*" (*Diamond Rubber Co.* v. *Consolidated Rubber Tire Co.*, 220 U. S. 428.)

The opinion gives RICHARDSON credit for discovering the phenomenon of pure electron discharge; yet Richardson himself makes no such claim; on the contrary in his book he speaks of the essential characteristic of pure electron discharge, the limitation of current by space charge, as "*an interesting effect which was discovered and explained by Langmuir,*" (Vol. IV, p. 339), citing Langmuir's *Physical Review* paper. *Richardson's law was not a law of the passage of current through a tube;* it was simply an expression of how electrons are boiled out of a heated filament.

The Court referred also to Child's 3/2 power law; this was a mathematical theory as to how currents might flow through ionized gas. But that had no bearing on Langmuir's invention; *the essence of Langmuir's invention is that there should be no gas to ionize.*

Fleming in his popular article casually speaks of a "high vacuum," by which he clearly means, as we have shown on pages 71 to 77 of our main brief, the vacuum of an incandescent lamp or of an X-ray tube, which is a matter of several microns. His own publication shows that when he said "high vacuum" he meant a vacuum in which the electrons *"ionize the residual gas"* (I. R., p. 1337). Fleming never suggested that a tube could be built in which current would flow from filament to plate without a gas conductor; on the contrary his *1916 book not only gives Langmuir credit for being the first to produce such* a tube, but shows that even at that date Fleming did not understand the characteristic difference between the old tubes and the Langmuir tubes.

Lilienfeld taught the world nothing so far as the production of a useful tube was concerned. Richardson in his 1921 book dismisses Lilienfeld's work as inconclusive (Main brief, p. 88).

All these references and many others were considered by the Law Examiner on the motion to dissolve the interference. We quote his conclusion (I. R., p. 2468):

> "It is not seen that any of the remaining references made fully available to the public by proper disclosure the device now claimed in the issue as reformed, or that the proposed combinations of references, *with results not suggested by any one of them,* were obvious. The fact seems incontrovertible that a substantial and valuable contribution to the art has been made and that, within the limits explicitly stated or necessarily implied in the claims retained, it is entitled to patent protection."

From 1904, when Fleming invented his valve, to 1912, when Langmuir entered the field, the only improvement was the DeForest audion of 1906; an improvement only in that it utilized a third electrode or grid. The art waited for Langmuir to invent the thing which superseded these devices, the thing which made modern radio possible.

Why if this thing was so obvious, was it left for Langmuir, the scientist? Why did it never occur to Fleming or DeForest, or some of the other practical men who were familiar with the needs of the Art? The lower Court says because the radio art was young, and there was no pressing need for such an improvement. But the art was not so young. Wireless telegraphy had been in practical use since 1898 (138 Fed., p. 671). If the art was in its infancy, it was because it was held back by the lack of proper appliances. *It would be in its infancy today if it still depended on the Fleming valve and the DeForest audion.*

But DeForest had in mind another use for his audion; as a telephone repeater. Here was a real need for a high vacuum tube; the thing which has made long distance telephony possible. He must have realized, as the Telephone Company engineers did, that the energy limit of the audion made it unsuitable for telephone use. A high vacuum was just what he needed. Why, if it was such an obvious thing to do, did not DeForest give the Telephone Company a tube which would answer the purpose? The only answer, of course, is that it was not obvious, and that DeForest had no conception of a tube which would function without gas, or of any way of avoiding the serious difficulties and limitations which were inherent in the audion.

2. THE DeFOREST PRIOR USE.

Yet in spite of this conclusive demonstration to the contrary, the Court holds the patent invalid because of prior knowledge and use by DeForest. This holding is based in part upon the supposed use by the witness Hewlett (not DeForest) of an audion with a B-battery of 67½ volts.

We have pointed out in our main brief, page 51, that on the very page of the record where Hewlett says that he had a B-battery of 45 cells, which the Court assumes to mean 67½ volts, he testifies that *he never used the whole of the voltage at once.* We have also demonstrated that even if 67½ volts were used, that would be no proof that the tube was a high vacuum tube. Hewlett's testimony that by heating the tube he was able to control the amount of B-battery used, shows conclusively that it was not (Reply brief, p. 23).

The lower Court also found, by a curious process of reasoning, that the Lamont tubes must have been high vacuum tubes, because Lamont heated the bulbs during the exhaustion, and this in the face of the *uncontradicted testimony* that the process which Lamont used was a prior-art process, incapable of producing a high vacuum tube. *Defendant had a tube exhausted by Lamont by what was said to be the same process—but never put it in evidence* (Rec., Vol. II, pp. 1060 to top 1063; see also p. 1042).

The error in the decision below on this DeForest defense is so clear and so serious, and so easily demonstrated and understood, that we are sure that this Court will wish to correct it.

3. THE ARNOLD DEFENSE.

Arnold's claims are refuted by his own statements and conduct (Reply brief, pp. 60-70). The fact that he used old DeForest audions in connection with his important demonstration in February, 1913, is of itself sufficient answer to his claim that he had conceived the invention and reduced it to practice in November, 1912.

Here was a demonstration staged for the benefit of the President and other high officials of the Telephone Company to determine the practicability of the transcontinental telephone to which the Telephone Company had practically committed itself in time for the opening of the San Francisco Exhibition. Because of the limitations of the DeForest audions the energy in the circuits had to be kept very low. For a laboratory demonstration, such as this was, where all outside interference could be eliminated, the energy was sufficient, but Arnold himself admitted that it was insufficient for an ordinary commercial line (Vol. II, p. 742). The demonstration, therefore, left much to be desired; the Telephone Company still faced the problem of improving the audion so that it would be capable of handling the energy required in an ordinary commercial line. If Arnold had conceived the invention and reduced it to practice in November, 1912, as he alleges, common sense tells us that he would have used it and made his demonstration a real demonstration of the commercial practicability of long distance telephony without any ifs or buts. This of itself is enough to dispose of Arnold.

THE SECOND AND FOURTH PATENTS.

The decision on the second patent is based on the assumption that when the thoriated tungsten filament was put in a tube it would produce the emission of the second patent. No witness testifies that it would. We have demonstrated in our little brief in Nos. 3800 and 3801 that it would not; we have shown that, without special treatment of the filament *combined with radical modification of the tube itself*, such a filament would function exactly as the old tungsten filaments function; that the second patent covers a new combination, leading to a new and remarkable result.

The fourth patent is held invalid on the very references which are disregarded in the consideration of the third patent. We are unable to understand why, not being effective against the third patent, they are effective against the fourth patent (brief in 3800 and 3801, p. 28). The real question of law involved in the issue on the fourth patent is not discussed in the opinion.

CONCLUSION.

In his recent speech in Dearborn, on the occasion of the Edison celebration, the President of the United States, himself an engineer of no mean attainments, spoke of Mr. Edison's invention of the incandescent lamp as "an outstanding illustration of the value of the modern method and system of invention, by which highly equipped, definitely organized laboratory research transforms the raw material of scientific knowledge into new tools for the hand of man."

We submit that Langmuir's invention is another such "outstanding illustration," and that Langmuir is, still in the language of the President's speech, another of the "great leaders who have converted the pure physics of electricity into a taxable product"; one of those "men who have that originality of mind, that devotion and industry to carry scientific thought forward in steps and strides until it spreads to the comfort of every home."

We realize that the record is heavy and that some of the matters discussed therein are complex. We believe that on a rehearing we can show the Court that the real issues are actually very simple, and that we can demonstrate that Langmuir has made a great invention and that the patent on that invention should be sustained.

In view of the importance of this case to the public, to Langmuir's assignee and to the assignee's many licensees, we respectfully ask the Court to grant a rehearing, and to stay the mandate pending the disposition of this petition.

Respectfully submitted,

Hubert Howson,
Albert G. Davis,
Ralph B. Evans,
Counsel for General Electric Company, Petitioner.

CERTIFICATE.

I certify that this petition for rehearing, in my opinion, is well founded in law and in fact, and that it is not filed for the purposes of delay.

Ralph B. Evans.

November 1, 1929.

APPEALS FROM THE DISTRICT COURT OF THE UNITED STATES FOR THE DISTRICT OF DELAWARE.

(Filed November 11, 1930.)

Before BUFFINGTON, WOOLLEY and DAVIS, *Circuit Judges.*

Buffington, J.

In the Court below the General Electric Company charged the DeForest Radio Company with the infringement of four patents. On final hearing that Court held one of the patents valid and infringed and the other three invalid. By appropriate steps its so holding was brought before this Court for review. Without entering into detail, we may say that, save as to patent No. 1,558,436, the reasoning, conclusion and decree of the Court below commend themselves to us and we affirm the same. In the case of patent No. 1,558,436, we feel the Court below committed error in holding the patent invalid and dismissing the bill.

As usual in litigation over a patent of great commercial value, the vast mass of expert speculation, the protracted argument covering days and with briefs that in the aggregate covered several hundred pages, the case, on re-argument, narrowed to the simple question of the patent paternity of what is known commercially as the Langmuir tube. The Court below held the tube had no patent paternity and to that question we now address ourselves. The subject matter of the patent and the general features of the pertinent art are set forth at length in the comprehensive opinion of the Judge below and by reference thereto we avoid the necessity of present restatement.

Laying aside for the present technical language and scientific discussion and confining ourselves to simple statement, the Langmuir tube is a tube in which for example the gaseous conductor incident to a Fleming valve and a DeForest audion is dispensed with and a vacuum substituted therefor.

In the patent sued on, No. 1,558,436, granted October 20, 1925, to Irving Langmuir, assignor to the General Electric Company for "electrical discharge apparatus and process of preparing and using the same," the specification states:

"The present invention relates to electrical *vacuum* discharge devices, and it comprises devices in which the electrical current is carried by negative charges called electrons, emanating from the cathode, independently of *gaseous ionization* such as occurring, for example, in the ordinary Roentgen tube.

"My present invention comprises improvements in electron-discharge apparatus which make possible a *high load capacity* and operation with the *highest voltages,* but the invention is also applicable and useful for moderate loads and moderate voltages."

Existing objectionable incidents to the use of gassy tubes and the erratic, non-determinable action of gas are pointed out as follows:

"In order to distinguish electron discharge devices made in accordance with my invention from the prior art, I will explain briefly the character of a *pure electron* discharge as distinguished from a discharge through *ionized gas.* In a Geissler tube, and in a Roentgen or Crookes tube the conduction of current is accompanied by and depends upon *gas ionization.* Without a certain *minimum amount of gas* a Roentgen X-ray tube ceases to operate and as this minimum is approached the resistance of the tube steadily increases.

"The passage of an electric current across a tube ordinarily involves the movement of negative charges called electrons which, under the influence of the impressed voltage, pass from the cathode to the anode through the *vacuous space.* If these electrons when moving above a certain velocity collide with *gas molecules* they tend to ionize the molecules, splitting them up into electrons and larger and more slowly moving ions. Under these circumstances the phenomena of conduction across the tubes are the result of the action and interaction of the electrons and the ions; these phenomena are in general *erratic and non-reproducible.* The cathode under these conditions is disintegrated, technically it is 'sputtered', which causes its rapid destruction. As *gas ionization* continues at higher voltages a *blue glow* may appear. The bombardment of the cathode by positive ions also causes heating of the cathode. The ionization of gases at low pressures by collision with electrons occurs at definitely determinable voltages, these voltages being known as the ionization voltages. *These voltages are different for different gases.* In the case of gases such as nitrogen, hydrogen, oxygen, argon, helium and neon, they are of the order of magnitude of fifteen to twenty-five volts."

Describing the DeForest audion and differentiating it from the alleged invention of the patent, the specification says:

> "The phenomena above described as being characteristic of devices involving *gas ionization* are taken advantage of in an incandescent cathode device with three electrodes known as the 'Audion.' This device has been used as a receiver for radio-telegraphy and depends in its operation upon the rapid change of the discharge current when *gas ionization begins*. This point depends upon various *accidental* conditions which cause such irregularities in the operation of various devices apparently identical that sometimes only one of a considerable number can be used. Ordinarily the gas ionization in the audion begins to be important somewhere between 20 and 30 volts."

Describing the Fleming valve and its limitations, the specification states:

> "Another discharge device previously used to some extent was the *Fleming valve*. This was a two-electrode tube which, so far as I am aware, was always used at voltages well below the voltages at which positive ionization by collision occurs. It was not evacuated in such a manner as to permit it to be used at voltages materially above these ionization voltages without manifesting substantial positive ionization effects."

Referring to high voltage, the specification makes this statement:

> "No prior hot cathode devices are known to me operating with currents as great as above 5 milliamperes with voltages as high as about 200 volts; indeed no prior discharge devices are known to me operating in a practically usable manner and without substantial positive ionization effects with currents as great as about one-tenth of a milliampere with voltages as high as about forty volts."

Specifying some of the differences and advantages of the alleged invention, the specification states:

> "In devices made in accordance with my invention *gas ionization* is either entirely *absent* or is negligible and a discharge takes place which is *distinct* in its characteristics from the described discharge taking place in an *ionized gas.* The cathode is not heated by the discharge itself. Blue glow, glass fluorescence and in fact all readily visible indications of a discharge are ordinarily absent."

Referring to the evacuation of the tube, the specification sets forth:

> "For the evacuation of the device the glass walls of the tube are carefully heated to as high a temperature as the glass will stand without softening and in general the most approved methods of incandescent lamp exhaust are used. The evacuation of the tube preferably while still heated is carried out by means of a suitable evacuating means, for example, a Gaede molecular pump, which removes *vapors as well as gases* . . .
>
> "The evacuation of the device should be preferably carried to a pressure as low as a few hundredths of a micron, or even lower, but no definite limits can be assigned. . . .
>
> "It is also true that when the anode has been carefully freed from gas, residual free gas, even if

present in a sufficient amount to cause some gas ionization when the apparatus is first started, does little harm, as it is quickly removed by the gas clean-up effect when the device is operated."

Claim 12, which is,

> "An electrical discharge device, comprising a gas-tight-envelope, an electronemitting cathode, an anode *deprived of ionizable gas* and a discharge controlling conductor, the space in the envelope being evacuated to a pressure not substantially in excess of a few hundred thousandths of a millimeter of mercury, said device being characterized by the fact that when operated below saturation and materially above the ionization voltages, the current is controlled by *space charge* substantially unaffected by positive ionization."

is typical in character of the alleged invention.

Does the defendant use a tube answering this general description? We think it does and that in giving up the old gaseous tube and using one of the "very high vacuum", a change which it announced in its statements to the public, we have a virtual admission of the essential difference between the two tubes. The tube of this disclosure is aptly described as "non gaseous" and "of a very high vacuum" by the defendant when putting it on the market, as follows:

> "The tube consists of a highly evacuated vessel, cylindrical, rather than bulbular, in shape enclosing the three elements, grid, plate and filament in the form of the old type T tubular DeForest tube with which amateurs are familiar. The plate is of nickel, cylindrical in shape and surrounds a helical grid also of nickel. The filament is a crimped tungsten wire passing through the center of the grid exactly as it did in the old style type DeForest tube. The chief difference between this tube and the type T tube of similar mechanical construction is in its evacuation. The old style type T was an *ionic or gaseous tube* very unstable in operation and requiring a variable 'B' battery.

It had the decided disadvantage that after continued use the tube would get 'hard' and require more 'B' battery until it reached such a state as to be inoperative. The new 'VT' tube, like the DeForest standard tubes to-day, is purely an electronic tube exhausted to a *very high vacuum,* so that it is non-gaseous and will stand very high plate potentials. When used as a detector, however, a battery of 20 to 40 volts is sufficient to give the proper plate current although voltages of 80 to 100 may be used without detrimental effect upon the tube. The 'B' battery moreover, is not critical in adjustment and, therefore, a fixed battery may be used and is used for all practical work. . . . The gaseous type tubes are, however, no longer being manufactured."

Turning next to the question on which the validity of the patent depends, we inquire first as to its usefulness, for the constitutional power to create the monopoly of a patent in that regard conditioned "to promote the progress of . . . useful arts" and the Congressional enactment in pursuance of the Constitution is that "any person who has . . . discovered any new and useful" etc. For in the final analysis, use, usefulness, is the acid test, the SINE QUA NON of patent grant.

The unusual degree of usefulness of the tube may be assumed. The defendant by its use evidences its usefulness and has, we have seen, adopted it and ceased making "gaseous type tubes," and the Court below, after its exhaustive study of the art, aptly described the tube, and we agree with its estimate, as an agency which "because of its stability, reproducibility and power has made possible radio broadcasting, modern radio reception and long distance telephony."

Seeing then we are here dealing with a progressive step which next to the telegraph, the telephone and the wireless, is probably one of the most far reaching and beneficent in human progress, there can be no question of a non-gaseous, vacuum tube's usefulness. Such being the case, is it novel? The simple fact is that we see such a tube in universal use to-day; we know in the quoted language of the Court below of its "stability"; of its "reproducibility"; of its "power." We know that these elements have, as stated by the Court below, made "possible radio broadcasting, modern radio reception and long distance telephony." Indeed the fact that a non-gaseous vacuum tube makes possible the present improved practice shows that such practice did not exist before the Langmuir tube and that no other device or devices, all important as they may have been in their spheres, did either singly or collectively produce the present practice. The patent office recognized that. In the opinion of The Board of Examiners they found, in affirming the decision of the Examiner of Interferences, that "Langmuir was the first to conceive and the first to reduce."

While all the vast mass of knowledge testified to in these records was open to everyone to use, the simple fact remains that the non-gaseous tube of modern use did not occur to scientists. Every one of the two hundred and sixty-six words in Lincoln's Gettysburg Speech is found in the dictionary; most of them in the Bible. But it remained—not for Noah Webster or even the Prophets of old—but for Abraham Lincoln to take these isolated words and so use them conjointly as to produce the most remarkable combination in literature.

We do not disregard or minimize the all important part of DeForest's audion and Fleming's valve play in the utilization of them in the Langmuir tube, but in spite of such high value, neither of them, in isolation or conjoint use, gave the world the tube here in question and it remained for Langmuir to so couple and coordinate the two by means of eliminating gas and using vacuum as to produce the tube here involved. What scientific credit is due to DeForest or Langmuir or to what patent tribute Langmuir subjected himself in thus using their devices are questions not before us.

Moreover the statement in the Commercial Circular of the DeForest Company that gas was an element of operation, was in accord with the then scientific belief. In 1911 Gernsback, an experienced savant, wrote that in the audion "the operating principle is the shattering of a column of conducting gas by a received electrical impulse."

The function of a gaseous tube as a conductor was stated by the Circuit Court of Appeals of the Second Circuit in 243 Fed. Rep. 565, where Fleming's valve and DeForest's audion were considered, in these words: "The 'gaseous medium' of the audion is nothing but the commercial vacuum of the ordinary electric light bulb—air being a gas, and the bulb containing some residual air. In other words, defendant uses the same 'vacuous vessel' that Fleming does." And in its opinion it stated that it was asserted in that case that the audion was "an apparatus in which the bulb contains a substantial amount of gaseous medium essential to the operation of the device." To the same effect is the testimony of Langmuir, of which we find no contradiction, that

> "In the devices of the old art, in the DeForest audion, the pressure was continually changing. It sometimes increased and it sometimes decreased. Both things went on and there was an evolution of gas, water vapor would come off the bulb and be decomposed by the filament and it would generate gas. Gases would come out of the electrodes. Positive ions would bombard the walls and the electrodes and would drive gas off."

It will also be noted this Court in its able and exhaustive statement of the art in 21 Fed. (2) 918, said: "We observe that at the time of both the DeForest and the Armstrong inventions the only audion tubes in use were 'gassy' or 'soft':"

That its action was eccentric, is shown by DeForest's statement:

> "In the first place, anyone who has had considerable experience with numerous audion bulbs must admit that the behavior of different bulbs varies in many particulars, and to an astonishing degree. The wing potential wing current curves for different bulbs, or even for the same bulb at different times, under different conditions (filament temperature, etc.) vary widely.
>
> "What may appear to be a fixed law for one bulb may not hold for another."

On the other hand, the current in Langmuir is practicable, steady, reproducible at any particular voltage.

It further appears that the Langmuir tube has a great advantage when it comes to replacement. When a tube is defective, another of the same type can be bought and placed in the same socket. Not so with the audion. It required frequent replacement and where replacements were made it was necessary to readjust throughout the circuit. In that respect the proof is:

> "XQ. 35. What practical effect would harmful ionization have upon an audion amplifier such as, for example, as is used in the telephone line?
>
> "A. The worst immediate effect would be as to uniformity of operation, which would make continued adjustments necessary and would interfere with the replacement of one device by another, that is to say, when one tube burned out and another were put in an amount of ionization that would interfere with uniformity of operation would make it necessary to readjust throughout the circuit to take care of the substitute tube."

As to the replacement, the proof is that

> "Another consequence of this uniformity is that replacement of the tubes without changing the apparatus becomes possible. That is particularly important in telephone repeaters and in radio devices both of the receiving and transmitting type. One wants to know that he can replace a burned-out tube with a new tube without having to make substantial changes in the apparatus."

It will also be noted that the whole trend of the art was against the use of a vacuum, and even after Langmuir had shown its use, it was deemed impractical. Thus in a paper of 1914 Wehnelt and Leibreich said that ionization persisted in the best vacuum they could get.

Moreover, it is of great present significance that the then view of DeForest himself was against Langmuir's use of the vacuum, he then stating in a paper read by him before a scientific body: "I believe, however, Dr. Langmuir has, by working into these high vacua and the high potentials necessitated thereby, pursued the less promising of the two paths of research." The record shows no explanation, comment or retraction by him of this statement.

Such being the general state of the case, has the defendant by evidence overcome the prima facies of the patent? We think not. As said by this Court in 159 Fed. Rep. 948, citing the Barbed Wire Case, "the burden of proof upon this part of the case rests upon the defendant, and every reasonable doubt should be resolved against it." And in our view the crux of the case is one of fact, namely, whether the use of a vacuum in the combination of the claim was Langmuir's novel disclosure. We are not concerned with scientific theories and speculations as to what might have been done or what could possibly have been done for, as well said by the Circuit Court of Appeals of

the Second Circuit in 298 Fed. Rep. 582, we sit "not as scientists, but as weighers of evidence." But we are concerned with the fact whether the combination of the claim which Langmuir disclosed was new. That some had bombarded anodes of X-ray tubes to get some of the gas out of them; that others had heated bulbs or used pumps to lessen the gas, may all be true, but none of them had produced the commercial tube which Langmuir gave to the public. And such actual contribution in use and not theory and possibility of speculation is, and of right should be, the decisive factor in patent reward. As was said by the Circuit Court of Appeals of the Second Circuit: in O Rourke vs Mc Mull
Fed. 933;

> "The keynote of all the decisions is the extent of the benefit conferred upon mankind. Where the court has determined that this benefit is valuable and extensive it will, we think, be difficult to find a well considered case where the patent has been overthrown on the ground of non-patentability."

We regard as of high evidential significance the statements made by the defendant in its circular to the public, already quoted. It will not do to brush aside and ignore it on the suggestion it was the work of some enthusiastic subordinate or sales agent. It was a deliberate statement of a great mechanical company of its ceasing to make and market a superseded article and to thereafter make and market a new and different one. No such change would in business practice be made by subordinates, but was, in the nature of things, the mechanical, scientific and commercial determination of a great business organization. In this statement the defendant recognized a "gaseous," non highly vacuum tube as new. As we have seen, it differentiated it from its "gaseous" tubes up to then made and publicly announced that such gaseous type tubes would no longer be manufactured. And indeed, that no such non-gaseous, highly vacuum tube existed is shown by the fact that the testimony of experts and the laborious research by the Judge below, whose industry is proverbial, did not disclose any such tube as both parties to this litigation now make and contend for the right to make, existed or had advanced the arts in question to this new standard of theretofore non-attained efficiency.

Such being the case, the defendant is driven to take the position—which found favor with the Court below—that in view of what existed in the prior art, that it required no invention to so utilize these things in the prior art to produce a non-gaseous, highly vacuum tube, and that this great progressive step was due simply to the art's natural advance and improvement.

But in point of fact no such advance toward a non-gaseous tube, as we are now told was to be looked for in the art, was actually made by the art. We would not be misunderstood. Advance, inventive and non-inventive, was being made in the art, but their efforts were in other directions. We would not detract from the great advance made by DeForest and exemplified by his audion and by Fleming with his valve, but great as these steps were—both separately and collectively—and we regard them as the foremost in the advance of the art in the sphere here involved—the gaseous tubes still continued to be used and the art generally regarded gas as incident, if not, indeed, indispensable to their use.

Indeed, had the art followed the caution of DeForest heretofore quoted, we would have no vacuum tube, a situation akin to that referred to by this Court in the Turbine case, 202 Fed. Rep. 932, where we said:

> "Finding, then, as we do, that the disclosures of the Moorehouse patent had no helpful bearing or practical effect on the impulse turbine art, and supported in that conclusion by the fact that its

vagueness is such that fair-minded witnesses in this record greatly differ as to what its disclosures really are, we are not warranted in attributing to it any effect in the way of vitiating, or even minimizing, the work of Curtis."

Now as it seems to us, the art, although it did not exactly know how the gas in gaseous tubes acted and just why it was able to so conduct, nevertheless continued to use it and regarded it as the indispensable means of conducting. As against this firmly entrenched teaching and practice of the art, Langmuir's suggestion of eliminating gas as a conductor was a radical change and even more so was not the substitution of some other tangible conductor, but the disclosure of supplanting the tangible gaseous conductor by the intangible conductor of a vacuum. Vacuums, per se, were of course known. DeForest's audion and Fleming's valve were equally known, but the suggestion of dispensing with gas and utilizing a vacuum between the two was as novel in practice as it was unlooked for in result. Indeed, shortly before the patent in suit was applied for and even though the use of a vacuum may possibly have been suggested, the director of the Research Laboratory stated in a paper read before the American Institute of Engineers: "In connection with this work of Fleming's, we have studied the effect of vacuum on the current, and also found that the presence of gas is necessary for this negative discharge." And that Langmuir's use of high vacua did not appeal to so practical and eminent a scientist as DeForest was evidenced by his statement, heretofore quoted, made even after Langmuir had made known his process publicly,—"I believe, however, that Dr. Langmuir has, by working into these extremely high vacua and the high potentials necessitated thereby, pursued the less promising of two paths of research." For the defendant to now contend that the use of these extremely high vacua by Langmuir was simply the natural and to be expected growth of the art is to credit the ordinary art with a scientific capacity which a master of the art like DeForest did not himself possess. If it was an obvious thing, as the Court below believed and decided, for the ordinary art to do away with gas and gaseous tubes and substitute high vacua therefor, surely such an extraordinary mind in that art as DeForest, when confronted with the substitution, would not have pronounced high vacua a mistaken path. Had the ordinary art followed the advice of this super ordinary adviser and leader and discarded the suggestion of high vacua, it would seem so far as the universally used non-gaseous tube is concerned, it would not be in use to-day.

But it is contended by the defendant and the Court below so held, that all that Langmuir did was simply to vary in degree the prior use of the vacuum and that a mere difference in degree does not constitute invention or to use the defendant's contention, the Langmuir tube is "nothing more or less than the identical thing of the prior art with possibly a little higher vacuum, depending on the specific use to which the device is to be put." Assuming the correctness of this general proposition, we think it is not applicable to the present case. In considering change in degree, the test is not the quantum or minimum of change made but the quantum of change in function and result which such change, great or small, effects. A great change may effect but a slight change in function and result, while a slight change may effect a radical difference in function and effect. The effect, the practical progress and use in the arts, are the aim and end of patent grants and where great results follow a change, the slightness of the change tends to emphasize and make all the more remarkable, unexpected and inventive the disproportionate result the slight change effects. It was the slight turn of a screw and the closer proximity of the diaphram that made the telephone diaphram the carrier of speech and gave Bell the due reward—not for the slight turn of the screw but for the great effect it wrought. But a vacuum, or indeed change of vacuum, isolated and standing by itself, is not the Langmuir invention, but it is a working tube in which all the elements, cathode, plate, vacuum, so co-ordinate and interwork that current flow is not affected by gas. We say not affected by gas because of necessity an absolute vacuum is an impossibility, but the degree of vacuum is such the current flow is no longer objectionably affected [illegible] gas. Just what the degree of vacuum shall be is dependent on several elements and, as stated in the patent, cannot be exactly stated. In that regard the specification says: "The evacuation of the device should be preferably carried to a pressure as low as a few hundredths of a micron, or even lower, but no definite limits can be assigned."

So regarding what we believe to be the basic question in the case, we limit ourselves to the foregoing statement of our reasons for our conclusion. But in thus limiting our discussion, we deem it proper to say that the numerous questions and considerations advanced in the case in other particulars, have been duly considered.

The decree of the Court below holding this patent invalid is reversed and the record remitted with instructions to enter a decree that the patent is valid and infringed.

(GENERAL ELECTRIC COMPANY v. DE-FOREST RADIO COMPANY)

WOOLLEY, *Circuit Judge,* dissenting:

I am constrained to dissent from the judgment of the court holding the Langmuir patent No. 1,558,436 valid. I have the same trouble that other tribunals have had throughout the twelve years of the patent prosecution and five years of the patent's life in finding precisely what Langmuir invented. My trouble, like that of others, has been increased by the difficulty which attorneys for the patent have had in defining the invention and by the difference between their definitions and the claims of the patent.

This is more than a mental disturbance, for manifestly a patent to be valid must relate to some invention, something patentably new and useful, and must disclose the invention so that a court, looking through the eyes of those skilled in the art, can see what it is.

The art—really two related arts—is that of wire and wireless telephony, the latter commonly called radio. The invention relates generally to an electron discharge device comprising the familiar vacuum tube in which the customary electric current is carried by negative charges called electrons from the cathode to the anode, sometimes associated with a grid, and relates particularly to a vacuum space so free from gases as to avoid ionization. If the parts and principles of the mechanical construction were new and the gas evacuation old, there might be invention; and also if the structure and its principles were old and the gas evacuation—high vacuum—were new, still there might be invention. But the essential parts and principles of the mechanism, comprising a tube, cathode, anode and grid, were old, and high vacuum in the tube also was old. So the inventor was forced to admit the presence of these old elements, yet, still insisting he had created something new, he was compelled to avoid the common art terms applicable to these elements and particularly that of "high vacuum" in disclosing his invention and use technical terms which, as I understand them, mean the same old things. With this necessarily general preface to a highly complicated situation arising out of a difficult art, I come to the matters in hand.

In an effort to find what Langmuir invented, it is well to begin at the beginning. I shall therefore turn to his application for a patent, for in that instrument must appear the substance of the invention as the basis for subsequent amendments and for the patent as it eventually matured.

A recital of the prosecution of a patent application through the Patent Office is dreary reading yet, in this instance, it shows quite clearly that even the applicant was far from certain what he had invented. Naturally I hesitate to say this about Irving Langmuir, a great physicist, yet, saying it with entire respect, I am convinced that the history of the application establishes that fact and therefore is pertinent to the ever present inquiry: What did Langmuir invent?

The patent issued on October 20, 1925. The application was filed on October 16, 1913; renewed March 14, 1916. These are critical dates. The original application contained five claims; two for process of removing ionizable gas from vacuum electron discharge devices, that is, in plain words, for obtaining a high vacuum, and three for methods of preparing such devices, and no claims for discharge devices themselves. The specification conformed to these claims, referred to the art, stated the problem, disclosed construction adapted to the operative principle of such tubes and showed how they can be "evacuated" of gases by heating the glass walls, heating and bombarding the metal parts thereby expelling occluded gases, and drawing off both free gases and expelled gases "by a suitable evacuating means, for example, a Gaede molecular pump".

It should be noted that when the application was filed in 1913 the radio art was in its infancy but that, in 1925, when the patent issued, the art had attained an amazing growth. It is pertinent to inquire what happened to the application during this span of twelve years during which the mysteries that had enveloped the early art were largely dispelled and replaced by a broad knowledge of its principles.

After the application was filed in 1913 it lay practically dormant for several years, the applicant filing enough amendments by additions and cancellations to keep it alive. Amendments to the specification occurred as follows: two in 1913; eight in 1914; one in 1915; five in 1916; three in 1917; three in 1919 and forty-five in 1925, the year the patent issued.

Amended claims were filed and additions thereto and cancellations thereof made as follows: four in 1913; fifteen in 1914; twenty in 1916; five in 1917; nine in 1919; five in 1921 and forty-two in 1925, the year of the patent.

Analyzing these amendments, it appears that the five original claims (which were for process and method) were at different times wholly cancelled. Late in the year 1913 Langmuir first made claim to invention of a structure or device, that is, to invention of a tube. This he did by four claims. The first was amended four times and cancelled in 1925. The second also was amended four times and cancelled in 1925. The third was amended four times and was not cancelled. The fourth was amended once and cancelled in 1925. Of the thirty-two claims allowed in the issued patent, four are for method and process, being amplifications of the original method and process claims cancelled; twenty-eight are for a device. Of these device claims one was filed by amendment in 1913; one in 1917; nine in 1919; three in 1921 and fourteen in 1925, the year the patent issued. Bearing on the question whether Langmuir knew and disclosed in 1913, or indeed in succeeding years, what he had invented, it is significant to note that during twelve years, and mainly in the latter part of that period when the art had grown and reached a high stature, he rewrote, by sixty-seven amendments, the major part of his specification and cancelled all the original method and process claims and by one hundred amendments added, changed and cancelled claims until finally he was allowed the thirty-two claims of which twenty-eight, the claims for a device, are entirely new. It would be instructive, yet impossible within the permissible bounds of an opinion, to trace the progressive changes from the method and process claims of the original application to the device claims of the matured patent. But device claims having been allowed, they inevitably bring into the case certain devices of the prior art of which two are presently pertinent.

Long before Langmuir applied for a patent, Fleming, an English inventor, brought into a very feeble art a practical electron discharge device, comprising a cathode and anode in a vacuum tube. Also long before Langmuir's application, DeForest improved on Fleming by producing an electron discharge tube which he described as an oscillation detector and called an "audion". The improvement consisted in adding a grid to Fleming's elements. The construction and functions of both devices are given in an elementary way in the opinion in Westinghouse Electric & Mfg. Co. v. DeForest Radio T. & T. Co., 21 Fed. (2d) 918, 919. The audion as conceived by Fleming and improved by DeForest at once became and has ever since continued to be the basis of the modern art of transmitting sounds great distances both by wire and through the air. Just here dates are important. A patent for the audion (No. 879,932) issued to DeForest in 1908. The audion vacuum tube was therefore in existence and its principles of operation presumably known by Langmuir when in 1913 he filed his application for a method of evacuating such a tube, although he had not seen one until that year. In 1912 or 1913, the American Telephone & Telegraph Company, committed to the operation of transcontinental telephony by the opening of the San Francisco Fair, acquired rights under the DeForest patent and, first exhausting the gas and heightening its vacuum, used the DeForest audion as an amplifying telephone relay, thus making possible the first transmission of vocal words from coast to coast by wire. In 1917 the DeForest Radio Telephone Company, assignee of the DeForest patent, granted (with certain rights reserved) a license to the Western Electric Company to make, use and sell the invention for certain purposes with the right to grant sub-licenses. In 1920 the General Electric Company, the plaintiff in this suit and the assignee of the Langmuir patent in suit, acquired through mesne conveyances a sub-license to make, use and sell the DeForest audion, DeForest Radio T. & T. Co. v. Radio Corporation of America, 20 Fed. (2d) 598, 599, 600, which (probably with a heightened vacuum) it did on a vast scale until the DeForest patent expired in 1925, the year in which the patent in suit, after twelve years of travail in the Patent Office, issued to Langmuir, assignor to the General Electric Company, for an electron discharge tube including the essential parts and now universally accepted principles of the Fleming-DeForest tube. The Langmuir patent now completely covers the field previously occupied by the audion of the expired DeForest patent, and will, on the decree of this court, continue to cover it for twelve years more; hence the importance of this litigation.

Turning to the patent as it issued, the specification must first be looked at, for it contains some references to the behavior of electricity in a vacuum tube, old and well known, which are necessary to an understanding of the case. First there is a description by words and diagrams of mechanism for a vacuum tube. If new, this, it would seem, is unimportant as the specific mechanism is not claimed. Its importance resides in the fact that the patented device comprises the three elements of the general mechanism found in the art—the cathode, anode and grid, variously positioned in a vacuum tube to get the best electrical result—and in the fact that, as I read the record, these three elements, separately and in combination, operate on the same principle in which they operated in the art. Describing their operation, as the art then knew it, Langmuir said:

"The passage of an electric current across a tube ordinarily involves the movement of negative charges called electrons which, under the influence of the impressed voltage, pass from the cathode to the anode through the vacuous space. If these electrons when moving above a certain velocity collide with gas molecules they tend to ionize the molecules, splitting them up into electrons and larger and more slowly moving ions. Under these circumstances the phenomena of conduction across the tubes are the result of the action and interaction of electrons and the ions; . . . . The cathode under these conditions is disintegrated, . . . , which causes its rapid destruction . . . . The bombardment of the cathode by positive ions also causes heating of the cathode. The ionization of gases at low pressures by collision with electrons occurs at definitely determinable voltages, these voltages being known as the ionization voltages . . . . (It should, for later use, be noted here that Langmuir said nothing about gas being a supposed medium for conducting electrons from one electrode to the other.)

"If for a given cathode temperature the voltage is sufficiently high to cause all the electrons emitted or liberated at the cathode to be drawn away, then a further increase in voltage produces substantially no change in the current. The current thus determined is called the saturation current, and the range of operation in which the current is substantially independent of the voltage or approaches this condition may be called the saturation range or more briefly designated merely as saturation. If for a given cathode temperature the voltage is not high enough to cause all of the electrons which are emitted or liberated at the cathode to be drawn away, the operation occurs in a range below the saturation range. Operation in this range may be spoken of as operation below saturation."

Predicated on these two definitions of ionization and saturation Langmuir by claim 2, which has been treated in this litigation as a typical claim, said that his invention is:

"A discharge tube having a cathode adapted to emit electrons and an anode adapted to receive said emitted electrons, the tube walls being fashioned or shaped to permit the direct passage of a useful proportion of said electrons from cathode to anode, the gas content or residue of said tube and the relation of the parts of the tube being such that the tube is capable of being so operated in a range below saturation and materially above ionization voltages that the space current is governed or limited by the electric field of said electrons substantially unaffected by positive ionization."

That, as I read it, simply means "high vacuum," for a tube properly fashioned and shaped by skilled workers and highly (thoroughly) evacuated of gases—

free and occluded—will in conjunction with a two electron group or with a group of two electrons and a grid produce these results; both groups, then and now, being in common use for different purposes by the ar and by the plaintiff itself.

For the purposes of this case, vacuum means gas evacuation, high vacuum means vacuum above the ionization point, and, by the same token, a high vacuum tube means a non-gaseous tube. If the language of the claims means high vacuum, it is prior art, for the art was entirely familiar with the fact and effect of such a vacuum; and if prior art, Langmuir invented nothing.

When the patent came into litigation in this case in the District Court of the United States for the District of Delaware the learned trial judge, having trouble with the claims, endeavored to get from the plaintiff a definition of the invention, asking time and again, as did this court on appeal: If not high vacuum, what is the invention? An answer to this question seemingly had its difficulties. The plaintiff, of course, could not say that the invention was high vacuum alone, or high vacuum in combination with Fleming and DeForest parts alone, for that would be an admission of old art and would instantly avoid the patent. It was forced to admit that the Langmuir device included all these old elements but claimed it included "something else." So, eventually, in order to show this something else—something new—it produced, under the insistence of the trial court, this carefully constructed definition of Langmuir's invention, on which the case was tried below and on which it was first argued and decided in this court on appeal:

"The Langmuir invention is a coordination of elements having a new functional relation between various factors, producing a new result. It is not a matter merely of maintaining a certain vacuum, far less of *producing* a certain vacuum which will be destroyed the moment the tube begins to operate. It involves primarily a relation between the shape, size and space relation or "geometry" of the parts of the tube and the nature and pressure of the gas therein contained, coordinated and adjusted with respect to the conditions of the electric circuit."

That, I surmise, would be a bad patent claim. However, as it was intended to describe the invention more clearly and more definitely than Langmuir had disclosed it in the patent claims I shall take it as it is written and try to find what it means. I discern in its generalization three factors: (1) gas pressure in the tube; (2) "shape, size and space relation or geometry of the parts of the tube"; and (3) the relation of one to the other.

The first factor of gas pressure, or, more properly, the lack of it, if it means anything, must mean a minimum of gas. This in turn means high vacuum. If it does not mean high vacuum there is no new vacuum factor of invention in the device, for low vacuum was old and that is an end to the case. If it does mean high vacuum then again it is not new, for high vacua, their uses and effect and how to produce them, were long known and practiced in the art.

The second factor, or "geometry," of the physical tube elements is not, so far as the claims reveal, involved in the invention. The physical elements themselves were old. This the plaintiff admits. Though differing in shape from some others, they are not claimed to be inventively novel in themselves. Indeed, each claim describes the invention not so much by its parts as by its characteristics of operation and results—characteristics inherent in any electron discharge tube possessing a high vacuum. Nor was this an inadvertence for when the Examiner, on rejecting certain device claims on prior art references, said:

"If applicant's device is an improvement over the reference he should define the difference by structural limitations," the applicant (Langmuir) replied by saying:

"The 'structural limitations' in this case are to be found in the *difference of vacuum.*"

So, thus far, the invention, with old parts and a high vacuum, gets back to the question whether there was invention in the "difference" between low vacuum and high vacuum, a difference existing in and known to the art.

The third factor, the relation of the two factors of gas pressure and physical parts, appears nowhere in the claim unless it be implicit in the words "the gas content or residue of said tube and the relation of the *parts* of the tube being such" as to produce a certain result. (Gas pressure is scarcely a *part* of a tube.) If it is so implied, Langmuir can not claim invention by implication. The claim therefore is void for inadequate disclosure. If it is not so implied, there is no claim for the third factor.

Whether I am right or wrong in this analysis of the plaintiff's statement of Langmuir's invention or in my disposition of its elements is not important for the validity of the patent depends not on the plaintiff's conception and definition of the invention but on the claims of the patent.

So I come back to the claims of the Langmuir patent to find Langmuir's invention. But before doing that I am arrested by still another entirely new definition of Langmuir's invention, this time made by the court in its opinion. The court did not adopt the plaintiff's definition of coordinating elements with functional relations but, stating that a non-gaseous electron discharge device did not exist before Langmuir, found the invention to reside in his producing a non-gaseous tube in place of a gaseous tube of the prior art or, in other words, in substituting a high vacuum for a low vacuum, the very thing which all along the plaintiff was forced to avoid in its definition because it was old. Without conceding its predicate, I agree with the court's succinct definition of the invention; but as the invention so defined was old I cannot agree to hold a patent for it valid.

It now appears, and I say this with entire respect, that in interpreting and sustaining the patent broadly for a non-gaseous tube the court has given the plaintiff more than it ever dared to claim. A high vacuum or non-gaseous tube being old, the plaintiff knew that an admission that the invention was a non-gaseous tube and nothing else would defeat the patent. Langmuir also must have known that a non-gaseous tube was old for otherwise, if he had believed he was the first to conceive and make one, he could, and doubtless would, have claimed it in a half dozen words: "A non-gaseous discharge tube," or "an electrical discharge device with a high vacuum tube," whereas in his original application for a patent he made no claim for a tube of that kind or, indeed, for a tube of any kind, the inevitable inference being that at that time he thought all he had invented was a new method or process of gas evacuation, that is, a new way to produce an old thing. But that the plaintiff realized the necessity of claiming for the invention something more than a high vacuum tube or non-gaseous tube is evidenced by its earnest and repeated contentions that Langmuir's invention, while including a non-gaseous tube—high vacuum—admittedly old, included "something else," that something else being disclosed by the remainder of the long claims and interpreted in its quoted definition. The plaintiff nowhere and at no time has claimed that Langmuir invented a non-gaseous tube per se. And wisely so, for it well knew that, while not in universal use, non-gaseous tubes were in commercial use before Langmuir for some purposes and that gas evacuations were as thorough as the instrumentalities of the art in 1913 would effect, and that was substantially above the ionization point, which is the crux of this case.

Returning to the patent claims and using claim 2 for convenience, it appears that the invention is an electron discharge tube which is capable of being operated below saturation and above ionization voltages. Langmuir called this a "pure electron discharge device"—"pure" because unaffected by gas ionization which is either entirely absent or negligible.

Electricity is an elusive subject. Therefore I shall, for the immediate purpose, restate in plain words, if I can, the theory of ionization.

Ionization is an effect produced by passing an electric current through gas which remains in a vacuum tube when it has not been thoroughly evacuated. The myriads of electrons, when passing from cathode to anode above a certain velocity, collide with and break up the molecules of gas present and charge the resultant broken parts or ions with positive charges of electricity. Thus electric reaction is inevitable. The ions (with their positive charges of electricity) fight against the electrons (with their negative charges) in the normal flow of the latter from cathode to anode resulting, at high voltages, in a blue glow which is the indication of bad action, a thing to be avoided. The central point of this statement is that ionization occurs at certain voltages in an electron discharge tube when, not being thoroughly evacuated, it contains air or gas, whether gas free in the tube or gas occluded in its parts and liberated by heat during operation. The amount of ionization depends upon the amount of gas present. Langmuir prescribed in his specification that occluded gas should be expelled from the tube parts; from the tube by heating its glass walls; from the cold electrodes by electron bombardment—the liberation of gas by the electric discharge itself; and from the incandescent cathode by the heat of an electric current; all old; and after this, that both the expelled gas and free gas should be pumped out of the tube during the heating process (old) by "a suitable evacuating means (old) for example, a Gaede molecular pump," then a new German invention.

Thus the capital requirement, if not the sole requirement, of Langmuir's claimed invention, is as nearly as possible to withdraw from the tube all gas, free and occluded; in other words, to obtain as high a vacuum as possible. When that is done ionization is avoided and a pure electron discharge follows. Was this new with Langmuir?

Langmuir was met in the Patent Office with the Law Examiner's statement that:

"It is apparent after a review of the record that there is no single element which is broadly novel in the assemblage of elements making up an electron discharge device of the character defined in the issue. *An evacuated tube having therein an incandescent electron emitting cathode and an anode was old prior to the filing of Langmuir's application, and methods of attaining high vacua, sufficient to give a relatively pure electron discharge in a properly designed tube were also well known and available to persons skilled in the art.*"

Was that statement of the Law Examiner correct? I think it was. Just here occurs my sharpest departure from the opinion of the court which is based, as I have before stated, on what I am constrained to believe is an erroneous theory or finding that all discharge tubes before Langmuir were gaseous and that Langmuir's invention is a non-gaseous tube.

If that was his invention, clearly he must have been the first to conceive it and reduce it to practice.

That the Examiner was right in saying that high vacua in electron discharge tubes were old before Langmuir and that a pure electron discharge—the inevitable result in a high vacuum non-gaseous tube and an impossible result in a gaseous low vacuum tube—also was old is sustained by many prior publications and patents. The same prior publications and patents contradict, I think, the court's holding that Langmuir was first to make and invent a non-gaseous tube. They are so numerous that it would not be permissible to quote them in an opinion. I shall therefore do nothing more than cite a few of them, ranging from 1881 to 1912, found in the record and to be used by anyone who should desire to check up this statement or who may be charged with the duty of re-trying the issue. They are: Lilienfeld, Fleming, Doane, VonBaeyer, Bissel & Hagen, Malignani, Edison, Dwyer, Duncan, Leonard, Soddy, Thatcher, Child; illumined by the testimony of Waterman and Chaffee.

On these references I stand; and on them I would hold the patent invalid for want of invention.

Passing from the literature and patents of the prior art as affecting the validity of the patent for want of invention, I come to the question of prior use. The trial court found the patent also invalid because of prior use by DeForest on evidence as to which there is little dispute on the facts as distinguished from inferences. The test is the voltage at which ionization ordinarily occurs in a "gassy" tube. It is given at from 20 to 30 volts. That is not disputed; they are Langmuir's figures.

Prior to August 1912, DeForest was the electrical engineer of the Federal Telegraph Company of California and was engaged in developing the transmission and reception of messages by radio. In this work he used his oscillation detector or audion then normally having a gas content. It was a "gassy" tube. But desiring to use it not as a detector but as an amplifier, as later it was almost universally used and indeed as made for that use by the plaintiff itself under license and by the Westinghouse Electric & Manufacturing Company, its sub-licensee, he had the audion exhausted of gas as far as it was possible in that day. That is, he sought and obtained as high a vacuum in the tube as existing means would produce. When the vacua were too low and the amplications poor he complained to the manufacturer and had the tubes re-exhausted. During that period (1910, 1911 and 1912) the Federal Telegraph Company used DeForest's amplifying audion at 54 and 67½ volts. This was possible only because he had exhausted the tubes of gas, which otherwise would produce ionization at 20 to 30 volts, and thereby heightened the vacuum above that danger line. This was "high vacuum" within the definition of vacuum above the point of ionization and was therefore high vacuum within the sense of those words as used in this case. It was not so high as that later attained by more modern means, for instance the Gaede molecular pump, which had just come into the art at the time of the patent application, referred to by Langmuir in his application and invented not by him but by Gaede. I agree with the court that DeForest did not then understand the change in operative principle for in later years he expressed views contrary to those advanced both before and after that time. But DeForest did change the vacua of his tubes in changing their function from detectors to amplifiers. Whether he knew the principle of the change is of no consequence. The fact is he did it. And he did it before Langmuir. And by doing it he got rid of the ionization of low vacuum and obtained, and put into commercial practice for nearly three years before Langmuir, the very electron discharge of Langmuir's claimed invention.

What I have said about the device claims applies equally to the method and process claims.

On the subject of validity as involving invention I shall conclude this phase of the discussion by referring very briefly to the claimed advance made in the art by Langmuir's invention, matter with which the plaintiff very earnestly began and ended discussion in its brief and at the argument and matter by which the court was impressed. Admittedly, when invention is in doubt—yet *only* when it is in doubt—favorable reception by the art may be placed in the scale. As the four judges who heard this case have divided evenly on the question of invention, I shall, for that reason only, assume there is doubt as to invention. The plaintiff says that today everybody uses "the Langmuir tube", a name given it not by the art (as the plaintiff frankly admitted at the argument) but by the plaintiff itself; that Langmuir, seeing through the mysteries of the art, made an invention that revolutionized the industry and made possible the transmission of sounds through the air for great distances which without his invention would be impossible.

Much litigation in respect to the radio art has drifted to this circuit. Oddly enough, in every case the plaintiff has claimed for his invention the whole credit for its growth. I am satisfied from the number of cases we have heard that the whole credit for the amazing advance of the radio art cannot be given to any one invention or even to a few of them. In truth, the art is the product of innumerable impulses. The original impulse was, of course, the vacuum tube appearing years ago in the incandescent lamp art. Another impulse given in the incandescent lamp art and transferred to the radio art was that of the Just and Hanaman unstable squirted tungsten filament displacing Edison's bamboo filament; still another was Coolidge's method for obtaining a filament of pure tungsten, strong and stable. Impulses in the radio art itself came from many inventors. At one time there were seven thousand applications for patents pending in the radio section of the Patent Office. To mention only one or two inventions, they include discharge devices of the Fleming two electrode type and the DeForest type with a grid added to Fleming, the feedback circuit invented at different times by DeForest, Armstrong, Langmuir and Meissner. There are many more, without any one of which it has always been said by the particular inventor that the art would have gotten nowhere. And now the plaintiff here says the same of Langmuir. Important and indeed great as some of these inventions were, no one of them is entitled to all credit for what has been accomplished in this great art, for the art has been impelled forward by hundreds of inventors and thousands of skilled workers. What Langmuir claims to have done—procured pure electron discharge above ionization voltages in tubes of the DeForest type—appears to me to be the natural growth of the art, begun by others before Langmuir and by them reduced to practice with means then available, and developed to their later perfection during the twelve years of his patent prosecution through the Patent Office.

I thought after the argument, and still think, the Langmuir patent invalid because of lack of invention and prior use. If I am wrong and the patent really involves invention, then, again, I think it invalid for, as I read the evidence, Langmuir was not the first and original inventor. On this point, to avoid repetition, I refer and subscribe to the opinion of Judge Morris holding on evidence substantially greater than the evidence in the interference proceeding that, if invention, Arnold was the first and original inventor.

And so this court, one judge dissenting, affirmed the decree of the District Court, on its opinion, holding the Langmuir patent invalid.

In due course the plaintiff filed a petition for rehearing based on this proposition:

"In simple language, Langmuir's invention consisted in taking out the conductor (gas) which was in the Fleming valve and the DeForest audion and putting nothing in its place; he dispensed with what was regarded as an essential element in the operation of the tube (gas) and by doing so made a tube which worked infinitely better."

The petition was allowed and the reargument was based on this entirely new statement of Langmuir's invention made for the first time four years after suit was brought, five years after the patent was issued and seventeen years after the application was filed. Of course if the facts asserted were facts established by the evidence there would be no doubt about what Langmuir did and no doubt that it was invention and, if claimed, no doubt he was entitled to a patent.

The plaintiff rests its proposition upon its own statement that "Both Fleming and DeForest depended upon the conductivity of gas as the fundamental basis of the operation of their tubes". It makes this statement without distinguishing between detectors and amplifiers and supports it by carefully selected quotations from scientific publications in the early days of the art ranging from 1905 to 1912 (one in 1915) when scientists were feeling for the theory of electron movement in electron discharge tubes, some of whom based it on conduction by rarified gases or air, some on conduction by ionized gases, and some not on conduction at all but on free passage of electrons through space in a high vacuum, that is, in the absence of gas or air. And in addition the plaintiff to support its statement points to an adverse criticism by DeForest in 1915 of Langmuir's "extremely high vacuum" quoted in the court's opinion. The plaintiff ignored all the testimony on the subjects of prior art high vacua and pure electron discharge, which means absence of gas as a conductor, their advantages and uses, to which I have previously alluded with citations.

Of course, if the belief and practice of the art were that gas conducts the electrons, that gas therefore is necessary to conduction and Langmuir discovered it to be wrong, that in fact gas is an enemy to conduction, and omitted gas as an element in his tube yet obtained the same or a better result, clearly he made an invention. These are the things which now the plaintiff and also the court say he did. But Langmuir did not say so. If that was his invention he should have disclosed it in his claims for we are called upon to judge the patent on Langmuir's disclosures, not on the plaintiff's definitions of his invention. To be sure, he did refer in his specification to several tubes—the Geisler tube and the Roentgen X-Ray tube—"whose operation depends upon gas ionization". He might, more or less correctly, have added to the list detectors with gas content, then and now in common use for certain purposes, whose usefulness depends on their sensitiveness and their sensitiveness on gas content. But he nowhere said in his patent that before his invention electron discharge tubes used for amplifying purposes in order more faithfully to reproduce sounds (one of the purposes of the DeForest audion and the thing we are dealing with in this case) depended on low vacuum or that the art regarded, as an essential element of such a device, gas as a conductor, for he probably knew the contrary was true. To show that the plaintiff's last definition of Langmuir's invention is without foundation in the evidence I refer to, but shall not repeat, what I have said about prior knowledge and prior use of high vacuum tubes. I shall endeavor, very briefly, to show that Langmuir by his own words contradicts the plaintiff's last definition of his invention and refutes the theory on which the court has in part based its judgment.

In Langmuir's original specification he stated that when there was enough gas in the tube to become ionized by the discharge of electrons "The positive ions (gas molecules) *take part* in the *conduction* of current, giving at first erratic readings on measuring instruments connected in circuit," which is what the plaintiff now says. Continuing, he said, that the audion, the DeForest tube, was a device that took advantage of that phenomenon. *But he cancelled the quoted statement before the patent issued.* At the trial he was examined with respect to that statement in his patent application and was asked whether the sentence would be true if it read; "The positive ions take part in the conduction of current by acting as *conductors* or carriers of current". He answered: "In my opinion the sentence would have *no sensible meaning* if the word 'conductor' was left in for *it is inconceivable that ions could be conductors of current.* I will, therefore, confine myself to the case where the positive ions act as 'carriers'. With this correction I can say that the statement would not have been true."

With this cancellation and explanation Langmuir rested. Neither by amendment nor in his testimony did he again advert to a prior art theory of gas conduction which the plaintiff now says "was regarded (by the art) as an essential element of the operation".

In the interference proceeding Langmuir testified with respect to the early work of Lilienfeld, as follows:

"Lilienfeld proved beyond question, I think, that he obtained discharges, in some cases at least, in which the effects that he measured *were not dependent upon gas ionization.* . . .

"Lilienfeld probably succeeded in obtaining a discharge *high vacuum substantially free from effects of positive ionization* in the device he described in his 1910 paper. . . .

"Lilienfeld in his experiments of 1910 heated the walls of the vessel, *he reduces the gas pressure to a low value,* and in some of his experiments *he heated his electrodes* by *electronic bombardment.* . . .

"*Heating of glass and electrodes, and exhaustion to low pressure,* are elements which were used by Lilienfeld and were known *prior* to Lilienfeld's article. . . .

"Factor No. 1 which I gave in answer to XQ84, viz., that the bulb should be heated *during* exhaust to a temperature materially higher than the operating temperature, was used by Lilienfeld in much of his work. . . .

"Factor No. 4, which is that which I gave in the first part of my answer to XQ87, refers to the lowering of the pressure to such a point *that a further lowering brings about no further change.* In many of Lilienfeld's experiments, this condition *was realized.*"

VonBaeyer stated as early as 1909 that his "experiments were of course carried out in the highest possible vacuum to avoid the influence of ionization". Langmuir admitted that "Wehnelt claimed that . . . currents of the order of 10 milliamperes could be obtained even in the highest vacuum".

Referring to an interview with Richardson in 1912 Langmuir said:

"Richardson . . . expressed himself as confident that even in the highest vacuum thermionic currents could still be obtained."

Langmuir admitted in the interference proceeding that "prior to 1912 (the year before his application) there were some experimenters who took precautions to remove gases from the walls, from vessels and from electrodes''.

This, I think, shows that the reargument, based on an incorrect premise, should leave undisturbed the court's first finding that the patent is invalid.

The plaintiff, however, prevailed. The court reversed its previous decision and will now enter a decree holding the patent valid. From the opinion announcing its judgment, in so far as it will reverse the decree of the District Court on the first (Langmuir) patent in suit, I dissent.

This is a long dissenting opinion. In view of the gravity of the Court's decision and its effect upon the art I make no apology for its length. I frankly admit that it is written with the hope that it will arrest the attention of the reviewing court.

Circuit Judge.

CLERK'S CERTIFICATE.

UNITED STATES OF AMERICA,
EASTERN DISTRICT OF PENNSYLVANIA, } *Sct.*
THIRD JUDICIAL CIRCUIT.

I, WILLIAM P. ROWLAND, Clerk of the United States Circuit Court of Appeals, for the Third Circuit, DO HEREBY CERTIFY the foregoing to be a true and faithful copy of the original transcript of record and proceedings in this court in the cases of:- No. 3799—General Electric Co. v. DeForest Radio Co., No. 3800—General Electric Co. v. DeForest Radio Co., No. 3801—DeForest Radio Co. v. General Electric Co., on file, and now remaining among the records of the said Court, in my office.

IN TESTIMONY WHEREOF, I have hereunto subscribed my name and affixed the seal of the said Court, at Philadelphia, this day of December, in the year of our Lord one thousand nine hundred and thirty and of the Independence of the United States the one hundred and fifty-fifth.

(Seal)

(Sgd.) WM. P. ROWLAND,
Clerk of the U. S. Circuit Court of Appeals, Third Circuit.

SUPREME COURT OF THE UNITED STATES

ORDER ALLOWING CERTIORARI—Filed February 25, 1931

The petition herein for a writ of certiorari to the United States Circuit Court of Appeals for the Third Circuit is granted. And it is further ordered that the duly certified copy of the transcript of the proceedings below which accompanied the petition shall be treated as though filed in response to such writ.

Vol. IV

UNITED STATES PATENT OFFICE.

IRVING LANGMUIR, OF SCHENECTADY, NEW YORK, ASSIGNOR TO GENERAL ELECTRIC COMPANY, A CORPORATION OF NEW YORK.

ELECTRICAL DISCHARGE APPARATUS AND PROCESS OF PREPARING AND USING THE SAME.

Application filed October 16, 1913, Serial No. 795,010. Renewed March 14, 1916. Serial No. 84,342.

To all whom it may concern:

Be it known that I, IRVING LANGMUIR, a citizen of the United States, residing at Schenectady, county of Schenectady, State of New York, have invented certain new and useful Improvements in Electrical Discharge Apparatus and Processes of Preparing and Using the Same, of which the following is a specification.

The present invention relates to electrical vacuum discharge devices, and it comprises devices in which the electrical current is carried by negative charges called electrons, emanating from the cathode, independently of gaseous ionization such as occurring, for example, in the ordinary Roentgen tube.

My present invention comprises improvements in electron-discharge apparatus which make possible a high load capacity and operation with the highest voltages but the invention is also applicable and useful for moderate loads and moderate voltages. The novel features of my invention will be pointed out with greater particularity in the appended claims.

Figs. 1 and 2 of the accompanying drawings, Fig. 2 being a partial view, illustrate two types of discharge devices embodying my invention; Fig. 3 is a fragmental view showing a cathode construction, and Figs. 4 and 5 are diagrams of electrical systems illustrating certain applications of my electron discharge tubes.

In order to distinguish electron discharge devices made in accordance with my invention from the prior art, I will explain briefly the character of a pure electron discharge as distinguished from a discharge through ionized gas. In a Geissler tube, and in a Roentgen or Crookes tube the conduction of current is accompanied by and depends upon gas ionization. Without a certain minimum amount of gas a Roentgen X-ray tube ceases to operate and as this minimum is approached the resistance of the tube steadily increases.

The passage of an electric current across a tube ordinarily involves the movement of negative charges called electrons which, under the influence of the impressed voltage, pass from the cathode to the anode through the vacuous space. If these electrons when moving above a certain velocity collide with gas molecules they tend to ionize the molecules, splitting them up into electrons and larger and more slowly moving ions. Under these circumstances the phenomena of conduction across the tubes are the result of the action and interaction of the electrons and the ions; these phenomena are in general erratic and non-reproducible. The cathode under these conditions is disintegrated, technically it is "sputtered", which causes its rapid destruction. As gas ionization continues at higher voltages a blue glow may appear. The bombardment of the cathode by positive ions also causes heating of the cathode. The ionization of gases at low pressures by collision with electrons occurs at definitely determinable voltages, these voltages being known as the ionization voltages. These voltages are different for different gases. In the case of gases such as nitrogen, hydrogen, oxygen, argon, helium and neon, they are of the order of magnitude of fifteen to twenty-five volts.

The phenomena above described as being characteristic of devices involving gas ionization are taken advantage of in an incandescent cathode device with three electrodes known as the "Audion." This device has been used as a receiver for radio-telegraphy and depends in its operation upon the rapid change of the discharge current when gas ionization begins. This point depends upon various accidental conditions which cause such irregularities in the operation of various devices apparently identical that sometimes only one of a considerable number can be used. Ordinarily the gas ionization in the audion begins to be important somewhere between 20 and 30 volts. Another discharge device previously used to some extent was the Fleming valve. This was a two-electrode tube which, so far as I am aware, was always used at voltages well below the voltages at which positive ionization by collision occurs. It was not evacuated in such a manner as to permit it to be used at voltages materially above these ionization voltages without manifesting substantial positive ionization effects. No prior hot cathode devices are known to me operating with currents as great as about 5 milliamperes with voltages as high as about 200 volts; indeed no prior discharge devices are known to me operating in a practically stable manner and without substantial positive ionization effects with currents as great as about one-tenth of a milliampere with voltages as high as about forty volts.

In devices made in accordance with my invention gas ionization is either entirely absent or is negligible and a discharge takes place which is distinct in its characteristics from the described discharge taking place in an ionized gas. The cathode is not heated by the discharge itself. Blue glow, glass fluorescence and in fact all readily visible indications of a discharge are ordinarily absent. In most devices of simple construction which embody my invention, the discharge current passing through a given space with the cathode at a sufficiently high temperature with respect to the voltages employed, varies directly with the 3/2 power of the impressed voltages. This 3/2 power law can be readily derived mathematically for a tube in which there is substantially no positive ionization on the assumption that the whole surface of the cathode is at a uniform potential, that the electrons escape from the cathode with negligible velocities and that the walls of the tube do not carry appreciable electric charges.

In most simple devices embodying my invention, these conditions are so well fulfilled that the current does vary in proportion to the 3/2 power of the voltage over wide ranges of voltage above the ionizing voltages. This means that if the logarithm of the current is plotted against the logarithm of the voltage, the resulting plot is a straight line whose slope is 3/2. Or, in many cases it is more convenient to make use of the equivalent relation, that the 2/3 power of the current plotted as ordinates against the anode voltages as abscissæ gives a straight line.

In devices in which there is substantial positive ionization, on the other hand, even when the pressures of gas are so low that only very small currents could be carried by positive ions, the currents begin to increase with voltage more rapidly than according to the 3/2 power law as soon as the anode voltage materially exceeds the ionizing potential of the gas.

In devices embodying my invention which have more than two electrodes, or with special constructions, as where the cathode is a filament, so long that it cannot be considered an equi-potential surface, the 3/2 power law may be more or less masked. However, the effects thus introduced will be readily understood by those skilled in the art, and appropriate methods of identifying the pure electron discharge can easily be found corresponding to the special construction. For example, when such tubes have more than two electrodes and the temperature of the cathode is sufficiently high with respect to the voltages employed, the discharge will usually be characterised by a linear relation between the 2/3 power of the total electron current from the cathode and the voltage applied to any other electrode, the remaining electrodes being kept at constant potential. Another test that can often be made with a three electrode tube is to connect the grid directly to the anode, or to the negative end of the cathode, and observe whether the current varies as the 3/2 power of the voltage.

If for a given cathode temperature the voltage is sufficiently high to cause all of the electrons emitted or liberated at the cathode to be drawn away, then a further increase in voltage produces substantially no change in the current. The current thus determined is called the saturation current, and the range of operation in which the current is substantially independent of the voltage or approaches this condition may be called the saturation range or more briefly designated merely as saturation. If for a given cathode temperature the voltage is not high enough to cause all of the electrons which are emitted or liberated at the cathode to be drawn away, the operation occurs in a range below the saturation range. Operation in this range may be spoken of as operation below saturation.

A change in the temperature of the cathode in a hot cathode device embodying my invention will produce no change in the discharge when the operation is below saturation, even though the ionization voltage is materially exceeded. That is, the current-voltage curve is not changed by a change in the cathode temperature under such conditions.

The discharge in devices embodying my invention is practically independent of the pressure when the pressure is below a certain value which depends upon the size and shape of the device and upon the current and voltage of the discharge.

As distinguished from discharges in the presence of positive ionization, the pure electron discharge is characterised by regularity and reproducibility with given conditions. In a device in which the conduction of current is purely electronic and the effect of positive ions is negligible, the conduction of current is governed, over a certain range, on the one hand by the effect of the impressed voltage, which tends to propel the electrons across the vacuous space, and on the other hand by the mutual propulsion of the electrons in the space, which tends to limit or inhibit the current. This last mentioned phenomenon, the current limiting effect of the electric field of the electrons on each other, termed the "space charge effect," is discussed and analysed by me in a paper read before the Physical Society on October 18, 1913, which was abstracted in the Phys-cal Review for November, 1913, and published in full in the Physical Review for December, 1913, and again published in somewhat modified form in the Physikalische Zeitschrift for April 1, and May 15, 1914. It is the basis of the 3/2 power law referred to herein.

The geometric proportions of the device also affect the amount of current which will pass with a given voltage, but as these conditions remain fixed for a given device they may be represented by a constant in an equation expressing the relation between the current and the voltage.

As stated above, the current (I) in the particular device described herein, when operating below saturation, will vary with the 3/2 power of the voltage (V), the equation being:

$$I = aV^{3/2}, \text{ (a being a constant)}$$

As is well known, if we produce a logarithmic graph of any equation in which one variable of the equation varies as a power of the other variable, as for example, an equation of the general form $y = x^n$. (as by plotting logarithms of x as abscissæ and logarithms of y as ordinates) we find that this graph is a straight line. Hence the relation between current and voltage in a device operating below saturation and by pure electronic conduction independent of gas ionization may be expressed by the statement that when with a sufficient electron emission the logarithms of the current values transmitted between cathode and anode are plotted as ordinates against the logarithms of the respective voltages impressed between cathode and anode as abscissæ; the slope of the line obtained does not ordinarily increase for increasing voltage values over a working range of voltages extending materially above the ionization voltages.

A substantial amount of positive ionization ordinarily causes the logarithmic plot of the current with respect to the voltage to bend upwardly and away from the 3/2 power line when the ionizing voltage is materially exceeded. The absence of a bend in the logarithmic plot at voltages somewhat above the ionization voltage is ordinarily a reliable indication that the tube is a pure electron discharge tube, though saturation complete or partial at voltages somewhat greater than the ionization voltages may prevent such a bend in the plot of an ionizing tube.

As above indicated, one of the indications of positive ionization is the occurrence of erratic readings in measuring devices connected in circuit with an electron discharge device under observation. Such erratic readings, of course, will produce a sudden change or discontinuity in the logarithmic graph plotted as above described, and any such irregularities will be more manifest when observed as deviations from a straight line than when the readings are plotted directly.

The effect of positive ionization upon the magnitude of the discharge is especially marked in that region of operation where the current is limited by the space charge effect already discussed, and changes in curvature of the discharge characteristics may occur as indicated unaccompanied by any visible evidence of ionization such as blue glow or the like. At saturation on the other hand, the discharge is ordinarily much less sensitive, and in fact the discharge may actually exhibit naked blue glow effects along with a flat or straight saturation curve.

Devices made in accordance with my invention may be used for various technical purposes, such as relaying and detecting currents, producing oscillations and rectifying alternating currents, and such devices may be made which will operate without substantial positive ionization at voltages far above the ionization voltages with currents thousands of times greater than the currents at which the devices of the prior art were operable without substantial positive ionization. Devices made and operated in accordance with my invention are capable of transmitting currents materially exceeding one-tenth of a milliampere without causing positive ionization to take any essential part in the operation of the device, though the voltage is materially above the ionization voltages.

Before describing the method of preparing my new type of apparatus, I will describe the structure of the apparatus illustrated by Figs. 1 to 3.

As shown in Fig. 1 the various parts of the apparatus may be mounted in a tube, or envelope 1, upon a pedestal 2, similar to the mount used in incandescent lamps. The cathode 3 is centrally located and may consist of a short straight filament not shown in Fig. 1, but indicated by the position of terminals 5, 6, and shown plainly in Fig. 3. The cathode shown in Fig. 2 consists of a V-shaped conductor. Either form may be used, the particular form of cathode being ordinarily determined by convenience of construction. Preferably the cathode conductor is held taut by a spring 7 to avoid contact of the cathode conductor with the grid by sagging when the metal is expanded at a high temperature. The filament 3 is mounted between two oppositely disposed supports, 9, 9′, in this case constituting a closed loop, which may consist of insulating material, such as glass or quartz, but in some cases may to advantage consist of metal. Upon this frame-work is wound a discharge-varying conductor 10, ordinarily called a grid. The turns of the wire are closely adjacent to each other and are also very closely adjacent to but are out of contact with the incandescent cathode. By means of this grid 10 potential may be applied to exert a static control upon the movements of the electrons. A negative potential applied on the grid reduces the flow of current from cathode to anode in proportion to the degree of negative charge. A positive grid potential assists and directs the flow of current from cathode to anode in proportion to the degree of its charge.

The supporting framework for the cathode and grid is attached to a rod 11, mounted upon the stem of the tube. Adjacent to the cathode and grid is the anode 12 which in the present case has been indicated as consisting of a wire strung in a zig-zag manner over hooks 13 upon fork-shaped supports 14 and 15, but it is not necessary that it should assume this particular form. Both anode and grid preferably consist of tungsten, but other refractory metals may be used. By constituting the anode a continuous conductor it can be conveniently heated by passage of current during evacuation of the device and for this purpose is attached to leading-in conductors 16 and 17. The grid is indicated in Fig. 1 as being attached to leading-in conductors 18 and 19 at opposite ends, although but one terminal is ordinarily necessary.

In some cases it is desirable to use a plate-shaped anode; Fig. 2 illustrates such an arrangement suitable particularly for rectifying alternating current. The tube itself and other extraneous parts have not been shown in Fig. 2, as they are similar to Fig. 1. The cathode construction has already been referred to and the anodes 20 and 21 also preferably consist of tungsten and may be connected electrically with each other. Current connections are made by conductors 22, 23, the supports 24, 25 being merely indicated. It will be noted that both in Figure 1 and Figure 2 the electrons are afforded a short and direct path from the cathode to the anode and that this path is so related to the position of the walls of the tube as to minimize the tendency for electrons to pass to the walls of the tube. In such a tube electron bombardment of the walls of the tube is avoided, together with the heating of such walls and the secondary emission of electrons therefrom which said bombardment causes. The energy of the discharge is delivered mainly, or entirely, at the anode, anodes, or upon other interior members instead of at the walls of the tube.

For the evacuation of the device the glass walls of the tube are carefully heated to as high a temperature as the glass will stand without softening and in general the most approved methods of incandescent lamp exhaust are used. The evacuation of the tube preferably while still heated is carried out by means of a suitable evacuating means, for example, a Gaede molecular pump, which removes vapors as well as gases. Chemical evacuating means such as electrically vaporized calcium or magnesium may also be used. Either before or during the evacuation the anodes may be heated, especially when the anodes are to be run at elevated temperature during the normal operation of the device. In this case the temperature is preferably carried close to brilliant incandescence. In the case of the structure shown in Fig. 1, the heating may take place by passing an electrical current through the wire 12. The heating, especially of solid anodes such as shown in Figure 2, may take place in a suitable vacuum furnace, the temperature preferably being raised to 2,500° C. or even higher. Bombardment is a very effective means of removing occluded gas from anodes.

The bombardment is carried out when the evacuation has proceeded to a high degree by applying a potential between the cathode 3 and the anode 12, Fig. 1, the value of which depends upon the character of the device. Care should be taken to use a voltage below that at which a blue glow appears as this indicates harmful gas ionization, and as already pointed out, sputtering and disintegration of the cathode accompanies or closely follows the blue glow phenomenon. The pump should be constantly operated to remove the gas. After the removal of the gas thus driven out the voltage impressed between the cathode and the anode, or anodes, as the case may be, is increased thereby driving out more gas. This process is continued step by step with a progressively higher voltage, the final voltage depending upon the character of the apparatus. In most cases the final voltage should be materially higher than the voltage at which the device is to be used in actual service. However, in the case of devices that use exceedingly high voltages, such as 50,000 volts or even higher, substantially all the gas may be removed from the anode without resorting to voltages higher than the normal operating voltage. In the case of a plate-shaped anode which cannot be readily heated by passage of current, the discharge voltage may be chosen great enough to convey sufficient energy to the anode to raise its temperature to redness or even higher, when the device is to be used with a discharge current adapted to heat the anodes.

After the metal has been freed from occluded gas reabsorption of gas will not readily take place even though it is exposed to the air or other gases. For example, anodes thus treated may be removed to other apparatus which then may be evacated with less electron bombardment of the anode or anodes.

The evacuation of the device should be preferably carried to a pressure as low as a few hundredths of a micron, or even lower, but no definite limits can be assigned. The residual gas pressure should be below the value at which ionization by collision will take place at the given working voltage and current, with its accompanying phenomena of blue glow, disintegration of the cathode, and so forth. When the cathode and anode are located in close proximity and the discharge confined to the region between the same, the permissible pressure is higher than when the cathode and anode are at some distance. It is also true that when the anode has been carefully freed from gas, residual free gas, even if present in a sufficient amount to cause some gas ionization when the apparatus is first started, does little harm, as it is quickly removed by the gas clean-up effect when the device is operated.

Electron discharge apparatus thus provided with a gas-free pretreated anode or anodes, may be constructed to handle currents at a very high voltage by proper mechanical design of the parts subjected to static strains, suitable proportioning of the parts and so forth as described, for example, in my application Serial No. 795,609 filed concurrently herewith upon which Patent 1,273,783 was granted on July 23, 1918.

The asymmetric conductivity existing between the heated and unheated electrodes of a device of the character described may be utilized for various technical purposes. Reference has already been made to the rectification of current. As shown in Fig. 4 an electron discharge tube may be used for detecting electromagnetic waves in radio-telegraphy. As shown in this Fig. 4 the grid *g* and heated cathode *c* of an electron discharge tube 26 are connected respectively to the terminals of the secondary of a transformer 27, the primary of which is included in the antenna circuit 28. The antenna is grounded through a condenser 29 in the usual manner. The cathode *c* is heated by a local source of energy, as battery *b*. A battery 30 in the grid circuit 31 has its negative terminal connected to the grid *g*. A condenser 32 shunts the secondary of the loosely coupled transformer 27. The inductance of the transformer and the capacity of the condenser are adjusted to make the receiving circuits resonant to the frequency of the oscillations to be received. The oscillations set up by the incoming signals are superimposed upon the negative grid potential and causes a variation of current transmitted between cathode *c* and anode *a* by a local source of energy such as a battery 33 included in the local or plate circuit 34, 35, of the discharge tube. This circuit is connected to an ordinary telephone receiver 36, preferably shunted by means of a condenser 37, whereby the signals are detected.

Fig. 5 illustrates how an electron discharge tube may be used in a system for producing alternating current from direct current. The anode *a* and cathode *c* are connected respectively to conductors 38, 39, one of which includes a local source of energy, such as a battery 40. The terminals of these conductors are connected to an inductive coil 41. The cathode and grid *g* are also connected respectively by conductors 39 and 42 to a second inductive coil 43 which may be in a variable inductive relation to the coil 41. As soon as a flow of current starts in the plate circuit 38, 39, current is induced in the coil 43 of the grid circuit 39, 42. When by reason of this current the grid becomes negatively electrified, the flow of current in the plate circuit is reduced, and as the plate current decreases the grid electrification changes to positive, which again allows the current in the plate circuit to increase. These changes take place with a frequency depending on the electrical characteristics of the circuits. Across the grid circuit 39, 42, of the discharge tube, in some cases is connected a condenser 44, the capacity of which may be varied to control the frequency of the oscillations set up by the system. The oscillations may be transformed to higher or lower voltage by a transformer coil 45 to the terminals of which are connected transmitting conductors 46, 47. The system shown in Fig. 5 is described and claimed in a copending application, Serial No. 797,087, filed October 29, 1913.

Residual gas, left in a tube when it is sealed off or occluded gas driven off from the inner wall of the tube, or from the electrodes, during the use of the tubes, varies in pressure from time to time according to the conditions of operation of the tube and may produce irregularities in the discharge when operating in the saturation region as well as when operating below saturation. The irregularities below saturation are due mainly to the disturbing effect of the resulting positive ions upon the space charge. The irregularities in the saturation region are due to changes in the rate of emission or liberation of electrons at the cathode. It is obvious that the advantages of stable and reproducible operation and freedom from destructive bombardment of the cathode by positive ions, which advantages are severally or collectively to be secured by the means hereinabove described, are not limited to operation below saturation but are also important in operation in the saturation region.

The positive ionization herein referred to is that positive ionization which occurs as the result of collisions between electrons and gas molecules in the space between the electrodes and causes, as by producing changes in space charge, unstable and non-reproducible operation.

What I claim as new and desire to secure by Letters Patent of the United States, is:—

1. A discharge tube having electrodes at least one of which is adapted to emit electrons, the gas content or residue of said tube and the relation of the parts of the tube being such that the tube is capable of being so operated in a range below saturation and materially above ionization voltages that the governing or limiting action on the space current due to the electric field of said electrons is substantially unaffected by positive ionization and by secondary electron emission from the walls of the tube.

2. A discharge tube having a cathode adapted to emit electrons and an anode adapted to receive said emitted electrons, the tube walls being fashioned or shaped to permit the direct passage of a useful proportion of said electrons from cathode to anode, the gas content or residue of said tube and the relation of the parts of the tube being such that the tube is capable of being so operated in a range below saturation and materially above ionization voltages that the space current is governed or limited by the electric field of said electrons substantially unaffected by positive ionization.

3. A discharge tube having electrodes at least one of which is adapted to emit electrons, the gas content or residue of said tube and the relation of the parts of the tube being such that the tube is capable of being so operated in a range below saturation and materially above ionization voltages that in that range the space current is governed by the combined effect of the electric field of said electrons and the potentials applied to said electrodes, the governing or limiting of the current being substantially unaffected by positive ionization and by secondary electron emission from the walls of the tube.

4. A discharge device comprising a tube and electrodes therein one of which is adapted to emit electrons, the degree of evacuation and the relation of the parts of the device being such that the device is capable of being so operated, when voltages materially higher than ionization voltages are impressed upon electrodes of the device and when the electron emission has any value such that the space current is below the saturation region at such voltages, that the slope of the line obtained by plotting the logarithms of values of said current as ordinates against the logarithms of the corresponding values of said impressed voltages as abscissæ shows no increase for increasing voltage values.

5. A discharge device comprising a tube and electrodes therein one of which is adapted to emit electrons, the degree of evacuation and the relation of the parts of the device being such that the device is capable of being so operated, when voltages materially higher than ionization voltages are impressed on electrodes of the device and when the electron emission has any value such that the space current is below the saturation region at such voltages, that the line obtained by plotting the logarithms of any values of said current below the saturation region as ordinates against the logarithms of the corresponding values of said impressed voltages as abscissæ is straight and continuous.

6. A discharge tube having electrodes at least one of which is adapted to emit electrons, the gas content or residue of said tube and the relation of the parts of the tube being such that the tube is capable of being so operated, when voltages materially higher than ionization voltages are impressed on electrodes of the tube and when the electron emission has any value such that the space current is below the saturation region at such voltages, that said current varies as the three halves power of said impressed voltages.

7. A discharge device comprising a tube and electrodes therein one of which is an electron emitting cathode, the degree of evacuation of said device and the relation of the parts of the device being such that the device is capable of being so operated, when voltages materially higher than ionization voltages are impressed on electrodes of the device and when the electron emission is such that the space current is below the saturation region at such voltages, that said current is substantially independent of the cathode temperature and unaffected by secondary electron emission from the walls of the tube.

8. A discharge tube having electrodes at least one of which is adapted to emit electrons, the gas content or residue of said tube and the relation of the parts of the tube being such that the tube is capable of being so operated in a range below saturation and materially above ionization voltages that the space current is governed or limited by the combined effect of the electric field of said electrons and the potentials applied to said electrodes, substantially unaffected by positive ionization, the heating effect in the tube due to said current occurring substantially only at one or more of said electrodes.

9. A discharge tube having a cathode adapted to emit electrons, an anode adapted to receive electrons and tube walls fashioned or shaped so as to permit the free passage

of a useful proportion of said electrons from cathode to anode, the gas content or residue of said tube and the relation of the parts of the tube being such that the tube is capable of operation with stable and reproducible results substantially unaffected by positive ionization, with currents of at least 5 milliamperes and with voltages of at least 200 volts.

10. An electrical discharge device comprising a gas-tight envelope, an electron-emitting cathode, a cooperating anode, and a discharge-varying conductor, the space in said envelope being evacuated to below the pressure at which deleterious gas ionization takes place, constituting a device in which the current passed when operated below saturation and over a working range of voltage materially above the ionization voltages is controlled by space charge substantially unaffected by positive ionization.

11. A high vacuum electron discharge device comprising an envelope, an incandescent cathode, and an anode, the space in said envelope being evacuated to such degree that the passage of current produces no appreciable positive ionization when the impressed voltage is as high as 200 volts

12. An electrical discharge device, comprising a gas-tight envelope, an electron emitting cathode, an anode deprived of ionizable gas and a discharge controlling conductor, the space in the envelope being evacuated to a pressure not substantially in excess of a few hundred thousandths of a millimeter of mercury, said device being characterized by the fact that when operated below saturation and materially above the ionization voltages, the current is controlled by space charge substantially unaffected by positive ionization.

13. An electrical discharge device comprising a gas-tight envelope, an electron emitting cathode, a cooperating anode, the space and materials in said envelope being sufficiently free of gas so that substantially no positive ionization occurs when the impressed voltage is as high as 60 volts, and the current over a working range of voltage up to 90 volts varies with the 3/2 power of the impressed voltage.

14. An electrical discharge device comprising a gas-tight envelope, a cathode adapted to be heated to incandescence, an anode from which substantially no ionizable gas can be evolved at operating voltages up to 100 volts with currents up to 1 milliampere, the envelope so shaped and the electrodes so positioned as to substantially avoid secondary electron emission from the wall of the envelope, the space in said envelope being evacuated to a pressure not in substantial excess of a few hundred thousandths of a millimeter of mercury.

15. A device comprising a gas-tight envelope, a cathode adapted to be heated to incandescence, an anode from which no ionizable gas can be evolved at operating voltages up to about 200 volts with operating currents up to about five milliamperes, the space in said envelope being evacuated at a pressure not in substantial excess of a few hundred thousandths of a millimeter of mercury, said device being characterized by the fact that with currents up to about five milliamperes at voltages up to about 200 volts, evidences of positive ionization are substantially absent and the current over a working range below saturation varies with the 3/2 power of the voltage.

16. An electrical discharge device comprising a sealed envelope, an incandescent cathode, and a tungsten anode, said anode deprived of ionizable gas disengageable by electron bombardment, and the space in said envelope being evacuated to a sufficiently low pressure so that current flow produces substantially no phenomena of positive ionization when the impressed voltage is as high as 100 volts and the current is as large as 1 milliampere, and the energy of the discharge is delivered mainly upon said anode.

17. An electron discharge apparatus comprising an envelope, an electron emitting cathode, and an anode, said anode being free of gas disengageable by electron bombardment and said envelope being sufficiently free of gas, so that conduction of current can take place in the evacuated space independently of gas ionization at voltages materially above the ionizing voltages with currents of more than one-tenth of a milliampere, and with the energy of the discharge delivered mainly at said anode.

18. An electrical discharge device comprising a sealed envelope, a cathode, means for producing emission of electrons at said cathode independently of the operating voltage, an anode, and discharge varying means independent of the cathode and anode, said device being freed from gas to such extent that the same is operable to transmit current at an impressed voltage at least as high as about 200 volts without evidences of substantial positive ionization.

19. An electrical discharge device comprising a sealed envelope, an incandescent cathode, an anode and discharge-varying means independent of the cathode and anode, the gas residues in said device being so small that the conduction of current is stable and reproducible over a range of voltage materially above the ionization voltages with currents in excess of one milliampere and with the energy of the discharge delivered mainly upon electrodes.

20. An electrical device comprising the combination of a sealed evacuated envelope, a cathode adapted to be independently heated, and an anode within said envelope,

an external circuit connected to said electrodes, and a source of electro-motive force applied to said circuit, the degree of vacuity and the electron emission of the cathode being so related to the potential of said source that the flow of current over a range of voltage materially above the ionization voltage is governed by the electric field of the electrons in the vacuous space and the potential applied to said electrodes, operatively independent of gas ionization.

21. Apparatus for controlling an electric current comprising a vacuum tube, an anode and an electron emitting cathode in the circuit of said current and within said tube, the degree of evacuation of the tube and the relation of its parts being such that for voltages materially above ionization voltage the current is governed or limited by the electric field of the electrons in said tube substantially unaffected by positive ionization, and a third electrode in said tube by which an auxiliary controlling electromotive force may be superposed to modify the effect of said electric field and control said current in a stable and reproducible manner.

22. The method of controlling an electric current in one circuit by an electromotive force in another circuit which consists in causing said current at voltages materially above ionization voltages to pass as a discharge across a vacuous space between an electron emitting cathode and an anode, maintaining a high vacuum in said space, governing or limiting the current by a space charge effect in said space substantially unaffected by positive ionization, and superimposing the effect of said electromotive force on said space charge effect to control said current in a stable and reproducible manner.

23. A discharge device comprising a tube and electrodes therein, one of which is a cathode, the discharge passing in the main directly between electrodes, the degree of evacuation and the relation of the parts of the device being such that the device is capable of being so operated below saturation and at voltages materially higher than the ionization voltages, that the slope or location of the logarithmic line of current with respect to voltage is not changed by changes in the temperature of the cathode.

24. A discharge device comprising a tube and electrodes therein, one of which is a cathode adapted to be heated and to emit electrons thereby, the discharge passing directly between electrodes, the degree of evacuation and the relation of the parts of the device being such that the device is capable of being so operated below saturation and at voltages materially higher than the ionization voltage, that the plot of the current against the voltage is not changed with changes in the temperature of the cathode.

25. A discharge device comprising a sealed off envelope having therein a cathode adapted to be heated independently of the dicharge and to deliver electrons thereby, and an anode, the inner wall of the envelope and the electrodes being sufficiently free of occluded gas, and the free gas within the envelope being such, so that the finished device is capable of sustained operation below saturation in a stable and reproducible manner with currents of more than one milliampere at voltages materially higher than the ionization voltages and with the energy of the discharge delivered mainly at an electrode or electrodes.

26. A discharge device comprising a sealed off envelope and electrodes therein, the envelope being shaped and the electrodes located so that the energy of the discharge is delivered mainly upon one or more of the electrodes, the inner wall of the envelope and electrodes being so free from occluded gas and the pressure in the tube being sufficiently low, with respect to the spacing of the electrodes and the energy of the discharge, so that the device is capable of passing a sustained discharge of one tenth of a milliampere at forty volts, without developing any substantial positive ionization effects.

27. A discharge device comprising a sealed off envelope and electrodes therein, one of which is a cathode adapted to be heated independently of the discharge and to emit electrons thereby, the inner wall of the envelope and the electrodes being so free from occluded gas that the device is capable of passing a sustained discharge of one milliampere at fifty volts with the energy of the discharge delivered mainly at an electrode or at electrodes without liberating any substantial amount of gas into the space within the envelope.

28. A discharge device comprising a sealed-off envelope and electrodes therein, one of which is a cathode adapted to be heated independently of the discharge and to emit electrons thereby, the inner wall of the envelope and the electrodes being so free from occluded gas that the device is capable of passing a sustained discharge of two milliamperes at one hundred volts with the energy of the discharge delivered mainly at an electrode or at electrodes without liberating any substantial amount of gas into the space within the envelope.

29. An electrical discharge device comprising a gas-tight envelope, a cathode adapted to be heated to incandescence, an anode from which substantially no ionizable gas can be evolved at operating voltages up to forty volts with currents up to one-tenth milliampere, the envelope so shaped and the electrodes so positioned as to substantially avoid secondary electron emission from the wall of the envelope, the space in said en-

velope being evacuated to a pressure not in substantial excess of a few hundred thousandths of a millimeter of mercury.

30. In the process of producing a discharge device, removing the occluded gas from the interior surface of the envelope thereof and from the electrodes to such an extent that the finished sealed-off device will operate, without liberating any substantial amount of gas into the space within the envelope, at voltages materially above the ionization voltage with currents greater than one milliampere and with substantially all the energy of the discharge delivered to an anode or anodes.

31. In the process of producing a hot cathode discharge device, treating the interior surface of the envelope and the operating parts to liberate therefrom occluded gas, and removing from the envelope gas liberated by said treatment and free gas originally contained therein, continuing these operations until the occluded and original free gas is so thoroughly removed as to enable the finished sealed-off device to operate below saturation in a stable and reproducible manner at a voltage above fifty volts and with a current greater than one milliampere and with the energy of the discharge delivered mainly at one or more anodes.

32. The process of producing a discharge device which consists in treating the envelope and enclosed parts thereof to liberate gas therefrom and removing from the envelope gas which is thereby liberated and free gas originally contained in the envelope, the treatment being sufficiently powerful and being sufficiently prolonged and the removal of the liberated and original free gas from the envelope being sufficiently thorough, so that the finished sealed-off device is capable of sustained operation substantially without positive ionization at voltages as high as one hundred volts with currents as great as one milliampere and with substantially the entire energy of the discharge delivered upon the anode or anodes of the device.

In witness whereof, I have hereunto set my hand this 15th day of October 1913.

IRVING LANGMUIR.

UNITED STATES PATENT OFFICE.

IRVING LANGMUIR, OF SCHENECTADY, NEW YORK, ASSIGNOR TO GENERAL ELECTRIC COMPANY, A CORPORATION OF NEW YORK.

ELECTRON-DISCHARGE APPARATUS AND METHOD OF PREPARATION.

1,244,216. Specification of Letters Patent. Patented Oct. 23, 1917.

Application filed July 15, 1914, Serial No. 851,085. Renewed June 25, 1917. Serial No. 176,926.

To all whom it may concern:

Be it known that I, IRVING LANGMUIR, a citizen of the United States, residing at Schenectady, in the county of Schenectady, State of New York, have invented certain new and useful Improvements in Electron-Discharge Apparatus and Methods of Preparation, of which the following is a specification.

The present invention relates to electrical devices operating with a pure electron discharge and comprises a novel cathode material and the method of its preparation.

In a previous application, Serial No. 795,610, filed October 16, 1913, I have described and claimed a new type of electrical discharge apparatus comprising an envelop containing electrodes one of which emits electrons and being so highly evacuated that positive ionization is negligible. Some of the characteristics of this "pure electron discharge" are absence of conductivity in the space between independent unheated electrodes, a variation of the current over a certain range with the 3/2 power of the voltage, the absence of blue glow in the space, the absence of gas fluorescence and the lack of cathodic disintegration.

Various refractory materials, platinum, carbon, tungsten and molybdenum, have been used as cathode materials and it has been found that the emissivity of electrons of these various materials while differing to some degree is of the same order of magnitude.

I have discovered that the electron emissivity of pure thorium is of an entirely different order of magnitude than the emissivity of refractory materials heretofore used in electron discharge devices. It is not necessary that the electrode should consist entirely of thorium. When, for example, a thorium compound, such as the oxid, has been added during the process of production to one of the highly refractory metals, for example, tungsten, and the metal subjected to a preliminary heat treatment in a high vacuum, the electron emission in a high vacuum is enormously increased. This increased emissivity is not due to the presence of thorium oxid in the manner of the Wehnelt cathode for various reasons hereinafter explained, but according to all indications is a property of metallic thorium on the surface of the cathode.

Apparatus suitable for preparing and utilizing a thoriated cathode in an electron discharge apparatus is somewhat diagrammatically shown in the accompanying drawings, in which Figure 1 shows a simple type of apparatus in which the anode consists of a film of refractory metal on the inside wall of the envelop produced by vaporizing a refractory metal at high temperature; Fig. 2 is a device operable as a rectifier having a thoriated cathode and plate-shaped anodes; and Fig. 3 illustrates a modification in which active thorium material may be transferred to the cathode from an independent thoriated conductor.

The device shown in Fig. 1 comprising an envelop 1 consisting of glass, quartz or the like provided with two filamentary conductors 2, 3, of highly refractory metal, such for example as tungsten, at least one of which, say filament 2, is thoriated. They are connected to leading-in wires 4, 5, sealed into a stem 6 in the well-known manner. The envelop is connected to a vacuum system by a tube 7, containing a trap 8 which may be surrounded by a freezing bath, such as liquid air, contained in a Dewar flask 9 or even an ice and salt mixture. It is the function of the freezing bath to prevent mercury, or other vapors, from the vacuum pumps from reaching the envelop 1.

The preliminary evacuation of the envelop is carried out by the usual methods of producing high vacuum, which includes baking out the envelop to remove water vapor. The final stage of the evacuation is preferably but not necessarily carried out by a Gaede molecular pump to the highest possible vacuum obtainable by this means,—that is, to about .001 micron. While the apparatus is still on the pump the filaments 2, 3, are heated to a temperature of about 2900° K. (absolute) for a short time and the envelop 1 is baked out in an oven at a temperature of about 360 to 450° K. The apparatus may then be sealed from the vacuum system at the contraction 10. It is then preferably immersed in liquid air and both filaments 2, 3 aged by heating for about ½ hour to a temperature of 2400 to 2500° K. One of the filaments, for example, filament

3, is then incandesced by a passage of current to a temperature of about 3000° K. which causes rapid vaporization of the metal, thereby producing a gas-free conducting deposit or coating 11 which has been shown on the inner surface of the envelop. Conductors 12, 13 sealed into the envelop make contact with this coating and enable it to be used as an anode for an electrical discharge. A device having a gas-free film anode and the method of its preparation has been described and claimed by me in a copending application, Serial No. 843,569, filed June 6, 1914. The method of producing high vacua by vaporizing tungsten is claimed by me in a co-pending application, Serial No. 838,768, filed May 15, 1914. Pressures much below .001 micron of mercury may be attained thereby. The cathode conductor 2 is prepared by introducing a thorium compound, such as the nitrate of thorium to the oxid of the refractory metal before reduction, or by adding either thorium nitrate or thoria to the metal powder after reduction but before consolidation of the metal by sintering and mechanical working to the solid metal state has taken place as described, for example, with reference to thoriated tungsten in U. S. Patent No. 1,082,933. The proportion of thoria in the unsintered metal usually varies from about ½ to 10% but in some cases may be even greater. The proportion of thorium compound in the cathode within the above limits makes little difference in the maximum electron emission that may be obtained under the best conditions but with a greater proportion of thorium compound the desired active condition of the filament may be reached and maintained with greater ease than with a lesser amount.

The thoriated cathode 2 is now heated to about 2900° K. for about one minute. The treatment of the filament at a temperature of 2900° has no marked effect on the subsequent electron emission of the cathode when at lower temperature but appears to be desirable for purifying the surface of the cathode. The cathode is then incandesced within the range of about 2000° to 2400° K. and by this temperature treatment some change is produced in the cathode which enormously increases its electron-emitting property under the condition described. The greatest activity is obtained between about 2200° to 2300° K. and the treatment at this temperature is usually continued for about one minute, but even outside of this range a marked change is produced. Apparently a concentration of metallic thorium or of some other oxidizable thorium material takes place on the surface of the filament. The filament 2 may now be used as a cathode at a temperature below this forming temperature.

With a filament thus prepared I have obtained at a temperature of about 1300° to 1380° K. substantially the same electron emission per sq. cm. as with a pure tungsten filament at about 2000° K., that is, about three milliamperes per sq. cm. Preferably a thoriated cathode is operated around 1700° to 1800° K., at which temperatures its life is indefinitely long.

Subsequently heating the filament to a higher temperature, for example, to 2800° K., causes some change, apparently a distillation of the film of thorium from the surface, as the electron emitting power of the cathode falls to the same order of magnitude as pure metal. When the cathode after being thus heated is re-subjected to a temperature of 2200° to 2300° K., the active condition is restored.

A similar heat treatment of pure tungsten has no effect on its electron emissivity at incandescence. The active thorium material may be transferred by distillation to an adjacent surface. For example, if the filament 3 consisting of pure tungsten has not been completely destroyed during the preparation of the apparatus, the heating of the cathode to a temperature above 2300° after the preparation of the surface film results in the distillation of some of the thorium material to conductor 3 so that when the conductor 3 is used as a cathode with respect to the anode 11, it is found that its electron emission has been greatly increased.

One of the most striking proofs that the active surface film is not due to the effect of the thoria as in the Wehnelt cathode is furnished by the effect of a minute trace of oxygen on the behavior of the cathode. If in some manner a trace of oxygen is admitted, the electron emission immediately falls as low or even lower than the low value observed when a cathode of pure tungsten is slightly oxidized. In other words, the electron emission becomes very much lower than that of the unoxidized metal. When subsequent to oxidation a trace of hydrocarbon vapor is admitted, the electron emission suddenly rises as though reduction were taking place. If the carbon is in excess, the electron emissivity immediately drops to a low value as though a carbid were formed with the excess of carbon. In an application Serial No. 58,377 filed by me on October 28, 1915, I have more fully described and also claimed a thoriated cathode device containing reducing material.

Cathodes containing only a small amount of thorium compound are deleteriously affected by disintegration of the surface produced by positive ion bombardment and in this respect may be extremely sensitive. In this case it is necessary when using voltages high enough to cause ionization of residual gases to carry the vacuum far beyond the point at which a disruptive discharge no longer takes place, which ordinarily is about $\frac{1}{10}$ of a micron of mercury pressure. The Wehnelt or oxid cathode apparently depends on positive ionization for its activity. At any rate its emissivity is increased by an increase in positive ionization. When large amounts of thorium are present in my improved cathode, it is not so sensitive to positive ion bombardment and it is possible to obtain to a large extent the advantages of a thoriated cathode even in the presence of pressures of gas up to atmospheric pressure.

Another proof that the high electron emission is due to a skin of thorium is the fact that metallic thorium itself, particularly when free from surface oxidation, exhibits a very high electron emissivity for a given temperature as compared with tungsten. Difficulties are encountered with the use of metallic thorium as cathode material due to its relatively low melting point and its susceptibility to oxidation.

At 2000° to 2300° K., the active thorium is slowly diffusing to the surface from the interior of the metal. As the temperature is raised a point is reached where the distillation of thorium from the surface exceeds the rate at which the metal diffuses to the surfaces. It is possible, however, to operate a refractory thoriated cathode at a temperature between 2000° and 2300° K. for a long time without destroying its high electron emission, but operation at a higher temperature is not advisable. A sufficiently great electron emission can be secured through the indicated temperature range with an accompanying saving of energy necessary for heating the cathode.

The apparatus shown in Fig. 2 does not differ essentially from the apparatus shown in Fig. 1, plate-shaped anodes 15, 16 consisting of a highly refractory metal such as tungsten being used instead of the film anode of vaporized metal used in the apparatus shown in Fig. 1. The envelop 17 is baked out and evacuated as already described in connection with Fig. 1. The ionizable gas should be removed from the anodes during the final stages of the exhaust after the pressure has been reduced below about $\frac{1}{10}$ of a micron of mercury by subjecting the anodes to an electron discharge from the cathode 18 whereby ionizable gas is evolved, as disclosed in my co-pending application, Serial No. 795,610 of October 16, 1913. This gas should be removed as fast as liberated and the discharge voltage progressively increased, care being taken not to materially exceed the voltage at which blue glow takes place so as to avoid injury to the cathode. The final stage of the evacuation is produced by vaporizing a tungsten conductor in a side chamber (not shown in the drawing), thereby producing the very high vacuum necessary for the operation of the thoriated cathode. The anodes 15, 16 may be both connected to one terminal of a secondary of the transformer 19, by conductors 20, 21, the cathode being connected to the other terminal by conductor 22, including a load circuit 23. The cathode 18 has been merely indicated by dotted lines as being a V-shaped filament supported by terminal wires 24, 25, and maintained taut at its bight by a spring 26, but it is to be understood that it may have any convenient form. Thorium compound, for example, the oxid, is introduced during the process of manufacture as already described. The apparatus here shown is suitable for the rectification of alternating current when the cathode is maintained at incandescence by a battery 27, preferably at a temperature of 1700 to 1800° K.

It is not absolutely necessary that the thorium should be introduced into the body of the metal during the process of manufacture. As shown in Fig. 3 a cathode 28 located opposite an anode 29 is provided with a film of active thorium material vaporized from the coiled filamentary cathode 30 heated by a battery 31. The cathode 30 may consist either of a thoriated cathode prepared as already described, or of metallic thorium. The inclosing envelop has not been shown, but it is to be understood that these parts are to be operated in the high vacuum already indicated as being desirable. When the coil 30 consists of thoriated wire it is first rendered active by heat treatment at a temperature of 2200° to 2300° K., as already described, and is then heated to a temperature of about 2900° K. to distil off active material, some of which is condensed on the cathode 28. When the coil 30 consists of metallic thorium, it should be heated to a temperature near its melting point to distil some of the thorium over on to the surface of the cathode 28.

As positive ionization is very much decreased at low voltages, it is permissible to have present an inert gas at a pressure of say .01 micron when the voltage impressed between the cathode and anode does not arise above the ionizing potential of the gas. Advantage can be taken of this fact to use an electron discharge device containing a thoriated cathode as a voltage sensitive cut-out device. Below the voltage at which disintegration of the surface begins, a device such as shown in Fig. 1 may be used to pass a current of about $\frac{1}{10}$ of an ampere per sq. cm. when the cathode is at a temperature of about 1700° to 1800° K. When the voltage rises above the critical value, the current immediately drops to a very small value, thus practically interrupting the circuit. The cathode may be restored when the voltage has fallen by again heating it to about 2200° to 2350° K.

What I claim as new and desire to secure by Letters Patent of the United States, is:—

1. In an electrical discharge device, an electrode comprising in part at least oxidizable thorium material, said electrode having at a temperature of about 1300 to 1380° absolute an electron emission substantially equal to that of tungsten at about 2000° absolute.

2. In an electrical discharge device, an electrode comprising in part at least oxidizable thorium and having when at incandescence in a vacuum so highly attenuated that positive ionization is substantially absent, an electron emission materially greater per unit of surface than tungsten at the same temperature.

3. A cathode for electron-discharge apparatus consisting largely of a highly refractory metal and a surface layer of material having an electron emissivity at a given temperature materially greater per unit surface than said refractory metal independently of and in the absence of positive ionization.

4. In a device operating by pure electron discharge independent of positive ionization, a conductor comprising a refractory metal and a surface film of thorium material vaporizable at a temperature above about 2300° K. and having a greater electron emission when at incandescence in a non-striking vacuum than said refractory metal.

5. In an electrical discharge device, an electrode comprising metallic tungsten and a surface film of thorium material vaporizable at a temperature above about 2300° K. removable from said surface by positive ionization and having an electron emission per unit surface many times greater than pure tungsten at the same temperature.

6. In an electrical discharge device, an electrode comprising metallic tungsten and thoria said electrode having been subjected to a temperature of about 2200 to 2350° K. and having an electron emission a thousand times as great per unit of surface as tungsten in a vacuum too high to permit of positive ionization.

7. In an electrical discharge device, a cathode comprising metallic tungsten and thoria, said electrode having received a heat treatment at about 2000 to 2350° K. and having an electron emission when at incandescence at a given temperature of a higher order of magnitude than pure tungsten at the same temperature.

8. The process of preparing an electrode comprising a refractory metal and thoria for use in a pure electron discharge apparatus which consists in heating said electrode to a temperature adjacent the melting point of said refractory metal and then heating to a temperature of about 2200 to 2300° absolute.

9. The process which consists in heating a conductor comprising tungsten and thoria to a temperature of about 2800 to 2900° absolute and then lowering the temperature to about 2200 to 2300° absolute holding said temperature for a short interval and finally operating said conductor as cathode in a non-striking vacuum at a temperature below 2000° absolute.

10. A cathode for electron discharge apparatus consisting largely of tungsten and containing thorium, said cathode having an electron emissivity, independently of and in the absence of positive ionization, at a given temperature materially greater per unit surface than tungsten at the same temperature.

11. In an incandescent cathode device, an electrode comprising a highly refractory metal and containing oxidizable thorium material, said electrode having an electron emissivity per unit surface many times greater than said refractory metal alone at the same temperature, the electron emissivity of said cathode being lowered by the presence of oxygen and by positive ionization.

In witness whereof, I have hereunto set my hand this 14th day of July, 1914.

UNITED STATES PATENT OFFICE

IRVING LANGMUIR, OF SCHENECTADY, NEW YORK, ASSIGNOR TO GENERAL ELECTRIC COMPANY, A CORPORATION OF NEW YORK.

ELECTRON-DISCHARGE APPARATUS AND METHOD OF OPERATING THE SAME.

1,244,217. Specification of Letters Patent. Patented Oct. 23, 1917.

Application filed October 23, 1915. Serial No. 58,377.

To all whom it may concern:

Be it known that I, Irving Langmuir, a citizen of the United States, residing at Schenectady, in the county of Schenectady, State of New York, have invented certain new and useful Improvements in Electron-Discharge Apparatus and Methods of Operating the Same, of which the following is a specification.

The present invention relates to electrical devices having an electrode consisting at least in part of thorium and having at a given temperature an electron emission per unit surface materially greater than the emission of a refractory metal such as tungsten at the same temperature independently of and in the absence of positive ionization. These devices are described and claimed in a copending application, Serial No. 851,095, of July 13, 1914, renewed on June 25, 1917, as application Serial No. 176,926, to which the present application is closely related.

In the preparation of these devices great care must be exercised to remove the last traces of oxygenous gases, particularly water vapor, and precautions must be observed not to evolve water vapor from the bulb walls during the operation of the device.

In accordance with my present invention, I have improved the above described device and also rendered easier the preparation of the same by providing in the envelop a quantity of a vaporizable reagent of low vapor pressure capable of preventing the oxidation of thorium. I prefer to use for this purpose an alkali metal, such for example, as potassium.

The accompanying drawing illustrates one particular form of apparatus to which my invention is applicable, namely, an incandescent cathode discharge device provided with means for introducing the desired reagent.

The device shown in the drawing which may be used for rectifying alternating current, comprises an envelop 1 consisting of a glass not chemically attacked by alkali metal provided with a cathode 2 consisting for example of thoriated tungsten, and a cylindrical or cup-shaped anode 3, also consisting of a highly refractory metal, such for example, as tungsten. A heating current may be conveyed to the cathode by leading-in conductors 4, 5, sealed into a stem 6 in the usual manner and connected to a threaded socket 7 similar to an incandescent lamp socket. The anode stem 8 is also sealed into a glass stem 9 and attached to an external metal cap 10.

The cathode 2 is prepared by adding a thoria compound, such as nitrate of thorium to the oxid of tungsten before reduction of the metal, or by adding either thorium nitrate or thoria to the metal powder after reduction, but before consolidation of the metal powder by sintering and mechanical working to the solid state as described, for example by reference to thoriated tungsten in U. S. Patent #1,082,933. The proportion of thoria in the unsintered metal usually varies from ½ to 10% but in some cases may be even greater. The proportion of thorium compound within the above limits makes little difference in the maximum electron emission that may be obtained under the best conditions but the favorable conditions will be more easily attained with a greater than with a lesser amount.

The preliminary evacuation of the envelop is carried out by the usual methods of producing a non-striking high vacuum, which includes baking out the envelop to remove water vapor. The final stage of the evacuation is preferably but not necessarily carried out by a Gaede molecular pump to the highest possible vacuum obtainable by this means, that is, to about .001 micron. While the apparatus is still on the pump the cathode 2 is heated to a temperature of about 2900° K. (2727° C.) for a short time and the envelop 1 is baked out in an oven at a temperature of about 360 to 450° C.

The substance to be distilled into the envelop, for example, potassium, is indicated at 12 in a small side chamber 13, a small quantity of glass particles, or glass wool, 14 being preferably placed in front of the reducing material. As already indicated all glasses (including the glass wool) used in the apparatus should be unattacked by alkali metal. When the envelop is baked out care should be exercised not to heat the chamber 13 to too high a temperature. The potassium, or other material, is transferred by melting into a communicating chamber 15, after which the chamber 13 may be sealed off. Thereupon, the material is distilled into a second communicating chamber 16 and finally a very small amount is introduced into the main envelop 1, both the chambers 15, 16 being successively sealed off. The redistillation of the reducing material serves to purify it. Although alkali metals have been indicated as preferable for the purposes of my invention, other reducing materials may be used, for example, hydrocarbon compounds. The bulb is finally sealed from the vacuum system at the contraction 11.

The thoriated cathode 2 is now heated to about 2900° K. for about one minute. The treatment of the filament at this temperature appears to be desirable for purifying the surface of the cathode. The cathode is then incandesced within the range of about 2000° to 2400° K. and by this temperature treatment some change is produced in the cathode which enormously increases its electron-emitting property under the condition described. The greatest activity is obtained between about 2200° to 2300° K. and the treatment at this temperature is usually continued for about one minute. Apparently a concentration of metallic thorium or of some other oxidizable thorium material takes place on the surface of the filament. The filament 2 may now be used as a cathode at or below this forming temperature.

The presence of the reducing agent in the main receptacle maintains the thorium reduced in spite of traces of water vapor which may be liberated from the glass. In any event the high electron emissivity of the thoriated cathode is more easily secured and maintained in the presence of the reducing agent than without it.

With a filament thus prepared I have obtained at a temperature of about 1800° to 1880° K. substantially the same electron emission per sq. cm. as with a pure tungsten filament at about 2000° K., that is, about three milliamperes per sq. cm. A thoriated cathode may be operated around 1700° to 1800° K., at which temperatures its life is long, and thermionic current may be obtained many thousands of times greater than obtainable with pure tungsten at the same temperature.

Subsequently heating the filament to a higher temperature, for example, to 2800° K. causes some change, apparently a distillation of the film of thorium from the surface, as the electron emitting power of the cathode falls to the same order of magnitude as pure tungsten. When the cathode after being thus heated is re-subjected to a temperature of 2200° to 2300° K. the active condition is restored.

The vapor pressure of potassium, sodium or other alkaline metal at room temperature is so low that objectionable positive ionization of its own vapor during the operation of the pure electron device is negligible and the vapor pressure of the oxidation products of the alkaline metal have no perceptible vapor pressure. For this reason, the alkali metals are to be preferred to carbonaceous compounds as reducing agents in the present device.

The vapor of alkaline metals does not produce an increased emission of a pure tungsten filament thereby furnishing proof that the beneficial effect of the alkaline metal is exerted upon thoria content of the filament and is not due to some ionization phenomena.

Under carefully controlled conditions the benefit of the increased electron emission of a thorium-containing cathode may be secured in a device filled with an inert gas, such, for example, as argon or other monatomic gases, at pressures ranging from a few millimeters of mercury pressure upward, in the presence of potassium or equivalent material for preventing the oxidation of thorium. Care must be exercised to have the cathode at a high enough temperature with reference to the current transmitted so that the vicinity of the cathode is surrounded by free electrons. In other words, the electron emission should be greater than necessary to convey the current thereby preventing a removal of the active thorium material on the surface of the cathode by a bombardment of positive ions.

What I claim as new and desire to secure by Letters Patent of the United States, is:—

1. An electrical discharge device comprising electrodes, one of which contains thorium, an inclosing envelop the space within which is evacuated to a pressure so low that positive ionization is substantially absent, and a quantity of a vaporizable reagent capable of preventing the oxidation of thorium in communication with the space within said envelop.

2. In an electrical discharge device, an inclosing envelop, a quantity of alkali metal within said envelop, and electrodes therein, one of which comprises in part at least, oxidizable thorium material, said electrodes having at a temperature of about 1800 to 1880° absolute an electron emission substantially equal to that of tungsten at about 2000° absolute.

3. In an electrical discharge device, an inclosing envelop, a quantity of potassium within said envelop, and electrodes therein, one of which consists largely of tungsten and containing thorium, said electrode having an electron emissivity at a given temperature materially greater per unit surface than tungsten at the same temperature.

4. An electrical discharge device comprising electrodes, one of which consists of metallic tungsten and a thorium material in an oxidizable state, an inclosing envelop, and a quantity of a vaporizable reagent within said envelop capable of preventing

the oxidation of thorium at an elevated temperature.

5. The process of improving the operation of an electron discharge apparatus containing an electrode operating at incandescence comprising a highly refractory metal and a thorium material which consists in bringing into contact with said electrode the vapor of a reagent preventing the oxidation of thorium at an elevated temperature.

6. The process of improving the operation of an electron discharge apparatus containing an electrode of tungsten and thorium operating at incandescence in a nonstriking vacuum, which consists in bringing into contact with said electrode the vapor of an alkali metal at a pressure too low to cause appreciable positive ionization phenomena.

7. An electrical device comprising the combination of a sealed evacuated envelop, a refractory cathode, means for heating said cathode to incandescence, a coöperating anode and a quantity of potassium within said envelop.

8. An electrical device comprising the combination of an evacuated envelop, a cathode, an anode and a quantity of alkali metal inclosed within said envelop, and means for heating said cathode to incandescence.

In witness whereof, I have hereunto set my hand this 27th day of October, 1915.

His Attorney

Patented Mar. 10, 1925. **1,529,597**

UNITED STATES PATENT OFFICE.

IRVING LANGMUIR, OF SCHENECTADY, NEW YORK, ASSIGNOR TO GENERAL ELECTRIC COMPANY, A CORPORATION OF NEW YORK.

ELECTRON-EMITTING DEVICE AND METHOD OF PREPARATION.

Application filed August 11, 1921. Serial No. 491,634.

To all whom it may concern:

Be it known that I, IRVING LANGMUIR, a citizen of the United States, residing at Schenectady, in the county of Schenectady, State of New York, have invented certain new and useful Improvements in Electron-Emitting Devices and Methods of Preparation, of which the following is a specification.

This invention comprises an improvement in the electron emitting cathodes of the type described in my prior U. S. Patents Nos. 1,244,216 and 1,244,217.

In these patents I have described the preparation and advantages of a vacuum tube containing a cathode adapted to be operated at incandescence and containing distributed throughout its mass thorium (or a compound of thorium) as a constituent. This type of electrode consists of a refractory conducting material, such for example as tungsten, with an addition of a material capable of increasing the electron emissivity of the cathode, such for example as thoria, the latter being subjected to modifications during the preparation of the cathode in the electron discharge device so that the active material in a finished device according to all indications, consists of metallic thorium or at least of a lower oxide of thorium than thoria (ThO_2). The cathode prepared according to the methods set forth in my first Patent 1,244,216 which is commonly known as a "thoriated cathode", is very sensitive to traces of oxidizing gas in the bulb, as for example, small traces of water vapor which may be given off from the walls of the bulb during the normal operation of the device. In order to prevent loss of activity of the cathode, I have described in my second Patent No. 1,244,217, the beneficial results obtained by the admission to the bulb of a small amount of alkali metal, such as potassium or sodium, or of a hydrocarbon compound.

My present invention in one of its aspects is based on the discovery that carbon in a cathode of the thoriated type, when present in a definitely limited amount, will prevent not only reoxidation of active thorium material but what is more important, will act beneficially to reduce thoria to the active state. Although the thoriated cathodes described in my prior patents can be used with satisfactory results, I have found that a further improvement in regularity and stability can be effected by using carbon as hereinafter described, not only as in accordance with my prior patent in restricted quantities, as an oxidation preventing agent, but, as hereinafter described, as an ingredient of a thoriated cathode.

In accordance with another feature of my invention my improved cathode is used in conjunction with a non-carbonaceous reducing agent which is provided in the bulb, as for example, a highly oxidizable metal.

A thoriated cathode may be deleteriously affected by positive ion bombardment, that is, when voltages materially higher than the ionization voltages are impressed between a thoriated cathode and a positive electrode in the presence of ionizable gas, then the beneficial effect of the thorium may be largely or entirely destroyed by positive ion bombardment. Although the alkali metals are entirely satisfactory as agents to remove deleterious gases when the operating temperature of the bulb is only moderately above room temperature, as in the case of radio receiving tubes, these alkali metals have a sufficiently high vapor pressure at the operating temperature of power devices in which cathodes of the thoriated type are used to become ionized at higher voltages and to cause removal of the active film of thorium from the cathode by bombardment. I have found that it is advantageous in many cases to provide a device containing a cathode of the thoriated type with a material having an affinity for gases, such as magnesium, for example, which at the operating temperature of the device, has substantially no vapor pressure. My invention will be pointed out with greater particularity in the accompanying claims and described fully in conjunction with the accompanying drawing which shows somewhat diagrammatically. An apparatus used for carrying out the preparation of an incandescent cathode rectifier.

The rectifier shown in the figure is illustrative of one of the various forms of incandescent cathode devices. It consists of a bulb 1 containing a filamentary cathode 2 into which thoria has been introduced as described in my above mentioned prior patents, and an anode 3, consisting of tungsten, molybdenum or other suitable material. These electrodes are respectively connected to lead wires 4, 4′ and 5 sealed into the walls of the bulb. The bulb is connected to the usual pumping system by means of a tubulature 6. The bulb also communicates with an elongated tube 7 adapted to be surrounded by a freezing mixture contained within a double-walled receptacle 8.

In carrying out my invention, the bulb 1 is first baked out as usual to remove water vapor and is then exhausted. Within the tube 7 is placed a substance adapted to give a low pressure of carbonaceous vapor, as for example, anthracene ($C_{14}H_{10}$) or naphthalene ($C_{10}H_8$).

When the vapor pressure of the substance employed is relatively high, I prefer to reduce the pressure of the hydrocarbon vapor in the bulb 1 by surrounding the tube with a freezing agent contained in the receptacle 8. When employing naphthalene, which has a moderately high vapor pressure, I prefer to reduce the temperature of the containing tube 7 to about —20 to —30° C. to reduce the vapor pressure to about 0.1 to 0.01 microns. The bulb 1 which communicates with the side tube 7, therefore, is filled with hydrocarbon vapor at approximately this pressure. The quantity of hydrocarbon may be controlled by one or more constrictions, such as 9, 10 which may regulate the pressure with or without a freezing agent.

The filament 2, which preferably consists of metallic tungsten, containing about ¾% thoria, is heated to a temperature of about 2300° K. (2000° C.) for a few minutes, in contact with the hydrocarbon vapor. At this temperature the incandescent filament decomposes the hydrocarbon vapor which comes in contact with the incandescent surface of the tungsten and causes the chemical combination with the tungsten of the carbon set free from the naphthalene vapor, with the formation of tungsten carbide (W_2C). The heating is continued for a length of time sufficient to give an increase in resistance of about 15 to 25% of the tungsten filament when cold, or at room temperature. This change in resistance corresponds to the presence of about two-thirds per cent of carbon by weight in the filament.

The carbon content most beneficial will vary with the conditions. In the case of a thoriated tungsten cathode all of the metallic tungsten will be converted to brittle tungsten carbide (W_2C) with a carbon content as high as 3%. Ordinarily a carbon content as high as about 1% is as high as permissible without unduly weakening the cathode. Although the presence of even minute amounts of carbon is highly undesirable in an incandescent lamp, a commercially long life can be obtained in a thoriated cathode containing carbon, as the cathode need be operated only at a relatively low temperature, say at about the operating temperature of an ordinary carbon lamp, the electron emissivity of a thoriated cathode being so much greater than that of an ordinary pure tungsten cathode. The hydrocarbon vapor is removed from contact with the filament either by sealing off the tube 7 at the contraction 9 or cooling the side tube 7 by means of liquid air in the receptacle 8 to a temperature so low that the vapor pressure of the naphthalene is negligible, thereby removing the naphthalene vapor from the bulb 1.

In some cases carbon in a desired proportion may be combined with the cathode prior to the introduction of the cathode into the bulb 1. For example, a thoriated filament may be prepared by squirting tungsten and thoria with a carbonaceous binder in amounts adapted to leave a suitable restricted proportion of carbon in the finished product.

As the next step in the preparation of the device, the anode 3 is deprived of gases by the usual method of electron bombardment; that is, by passing a discharge between the cathode at incandescence and the anode, the exhaust pump in the meantime being operated to remove the vapors and gases which are liberated. During this step some of the carbon is removed by oxidation and evaporation from the cathode but with an original carbon content of about ⅔ of one per cent, enough carbon remains subsequently to furnish a supply of active thorium material by reduction of the thoria.

After the cathode has been provided with a content of reducing agent a non-carbonaceous material capable of combining with water vapor and other deleterious gases may be introduced into the bulb. In some cases this non-carbonaceous reducing agent may consist of alkali metal, such as sodium or potassium. Cæsium may be used to advantage in some cases, especially when some positive ionization is desired in the electron discharge device. Cæsium can be conveniently provided by adding a mixture of cæsium halide and metallic calcium as a paste to some part of the bulb, this method of introducing an alkali metal being claimed in an application, Serial No. 608,311, December 21, 1922, by Ernest E. Charlton.

When not desiring ionization of residual gases or vapors, I prefer to introduce for the reasons given above a reagent having a lower vapor pressure than the alkali metals, as for example, an alkaline earth metal such as magnesium, calcium, strontium, or the like. Conveniently this is done by providing within the bulb a small heating coil 11, consisting of tungsten or other suitable refractory material, and containing a small quantity of the metal to be vaporized. Preferably I employ metallic magnesium. By heating the tungsten filament 11 with current conducted thru the lead wires 4, 12, some of the magnesium is volatilized and deposited on the inner surface of the bulb which is then sealed off at the contraction 10. As during the sealing off process there is a tendency to drive out a small quantity of gas from the heated glass, I prefer to heat up the filament 11 the second time, to volatilize a small additional quantity of magnesium, or the like, in order to combine chemically with what little gas may have gotten into the bulb during the sealing off operation.

The film of magnesium, or other equivalent metal, on the walls of the bulb will combine with any water vapor or oxygen which may be given off by the bulb, or any other parts of the device during its operation, and thereby prevent an oxidization of the active thorium material upon the surface of the cathode.

The tungsten cathode 2 is preferably heated for a very short time to about 2700° K. to volatilize any thorium oxide on its surface.

As a final step, the cathode is "activated", that is, brought into its highly active state by heating to a temperature of about 2200° K. for a few minutes. This results in the reduction of thoria by the carbon and causes the active thorium product to come to the surface of the cathode where it will be effective in increasing the electron emission during the operation of the device. The tube is then ready for operation.

As explained in my prior patents, a temperature materially higher than the activating temperature will result in the thorium being volatilized from the surface of the cathode. A fresh supply can be produced and caused to accumulate upon the surface by again activating or "forming" an electrode at about 2200° K. During normal operation, the cathode is heated to a temperature below about 2200° K. and as high as 2100° K. Under these conditions, the electron emission stays constant.

What I claim as new and desire to secure by Letters Patent of the United States, is:—

1. In an electron discharge device, a cathode body of the thoriated type containing carbon in an amount insufficient to convert all of the metallic constituents of said cathode to a carbide but sufficient to render said cathode less sensitive to the deleterious effect of gases than a cathode body unprovided with carbon.

2. In an electron discharge device, a tungsten cathode of the thoriated type adapted to emit electrons when heated, containing carbon in an appreciable amount but less than three per cent by weight.

3. A cathode adapted to emit electrons at incandescence comprising tungsten, about three-quarters per cent thorium and about two-thirds per cent by weight of carbon.

4. The method of increasing the electron emissivity of an electrode of the thoriated type which consists in introducing carbon into said electrode in amounts insufficient to convert said metal to a carbide, sealing said electrode into a space substantially free from carbonaceous vapors and thereupon activating said electrode.

5. An electric discharge device comprising an evacuated envelope, electrodes therein one of which comprises a refractory metal, thorium oxide and carbon in an amount insufficient to convert said metal to a carbide, and a non-carbonaceous reagent capable of combining with deleterious gases in said envelope.

6. An electric discharge device comprising an envelope, an anode and a cathode of the thoriated type and a non-volatile material, which is capable of reducing thorium oxide, contained in said cathode in such small amounts that the durability of said cathode is not appreciably decreased.

7. An electric discharge device having a cathode comprising metallic tungsten, thorium oxide and carbon combined with said tungsten in an amount materially less than required to convert all the tungsten to a carbide.

8. The method of increasing the electron emissivity of a cathode of the thoriated type which consists in introducing carbon into said cathode in an amount less than about one per cent by weight, heating said cathode in a non-carbonizing and non-oxidizing environment to a temperature at which a carbide of said metal is formed, activating said electrode by heating to about 2200° K. and operating the same under such conditions that bombardment of the electrode by positive ions is inappreciable.

9. The method of increasing the electron-emissivity of a cathode of the thoriated type which consists in introducing carbon into said electrode in an amount less than one per cent by weight, mounting said electrode in a bulb, evacuating the same, volatilizing magnesium in said bulb after evacuation, and activating said cathode by heating to an elevated temperature.

10. The method of preparing an electrode adapted to emit electrons at incandescence which consists in heating a conductor comprising refractory metal and thoria in a carbonaceous vapor to a temperature adapted to cause combination of carbon with said conductor, removing said vapor before the amount of carbon introduced into the filament exceeds one per cent, and heating said conductor in a non-oxidizing environment to a temperature at which electron emissivity is markedly increased.

11. The method of preparing an electrode adapted to emit electrons at incandescence which consists in heating to incandescence a conductor comprising tungsten and thoria in a carbonaceous vapor until a marked increase in cold resistance occurs by the introduction of carbon, discontinuing the heating before the tungsten has been largely converted to a carbide, and heating said conductor in the absence of said vapor in a reducing environment to produce a surface layer of thorium material having a markedly higher electron emissivity than the original conductor.

12. An electrical discharge device comprising a sealed envelope, electrodes therein which include a cathode of the thoriated type and a substance, having a marked chemical affinity for water vapor, deposited as a film of extensive surface upon the inside of said envelope, said substance having a materially lower vapor pressure than the alkali metals.

13. An electrical discharge device comprising a sealed envelope, electrodes therein one of which is of the thoriated type and a film of magnesium deposited on the inner surface of said envelope.

14. An electron discharge device containing a cathode of the thoriated type, said cathode being provided with a reducing agent sufficient in quantity to promote activation of said cathode, but restricted to an amount which will permit operation of said cathode at a temperature of effective electron emission with a commercially long life.

15. A cathode of the thoriated type for electric discharge devices containing less than about three per cent by weight of carbon.

16. An electric discharge device comprising an envelope, electrodes therein one of which comprises a refractory metal, a material reducible by carbon to a state of higher electron emissivity than said refractory metal at a given temperature, and a quantity of carbon in an amount insufficient to convert said metal completely to a carbide.

17. An electrical discharge device comprising a container, electrodes therein one of which contains less than three per cent of carbon combined therewith and a material capable of materially higher electron emissivity at a given temperature than the main constituent of said electrode, but being sensitive to positive ion bombardment, and a quantity of alkaline earth metal deposited in said container out of immediate contact with said electrodes.

18. An electrical discharge device comprising a container, electrodes therein one of which contains a material capable of materially higher electron emissivity at a given temperature than the main constituent of said electrode, but being sensitive to positive ion bombardment, and a quantity of alkaline earth metal deposited as a film on the inner surface of said container.

19. An electrical discharge device comprising a container, electrodes therein one of which contains a material capable of materially higher electron emissivity at a given temperature than the main constituent of said electrode, but being sensitive to positive ion bombardment, and a quantity of magnesium deposited as a film on the inner surface of said container out of immediate contact with said electrodes.

20. An electrical discharge device comprising a container, electrodes therein one of which consists largely of refractory metal and contains an oxide of a metal of high electron emissivity which when rendered active is sensitive to ion bombardment together with a reducing agent, and a quantity of alkaline earth metal, the latter being deposited as a film on the inner wall of said container.

21. An electrical discharge device comprising a glass bulb, electrodes therein one of which consists largely of refractory metal and contains a material capable when activated of substantially increasing the electron emission of the electrode with which it is associated but which is deteriorated by oxidation and positive bombardment, and a film of magnesium coating the inner surface of said bulb.

22. An electrical discharge device comprising a container, electrodes therein, one of which contains as a constituent a material capable of higher electron emission than the main constituent of said electrode but which is sensitive to positive ion bombardment, and to the chemical effect of water vapor under operating conditions, and a film of metal deposited from the vapor state in a vacuum on the wall of said container which metal has a high chemical affinity for water vapor and has a materially lower vapor pressure at the operating temperature of said device than the alkali metals.

23. The method of increasing the electron emissivity of a metallic electrode containing a compound capable upon reduction of materially increasing the electron emissivity of said electrode which consists in introducing carbon into said electrode in an amount insufficient to convert the metal constituting said electrode completely to a carbide and heating said electrode in a non-oxidizing and non-carbonizing environment to a temperature sufficiently high to activate said electrode, and thereupon operating said electrode under conditions which render the effect of positive ion bombardment of said electrode inappreciable.

24. An electrode material for an electrical discharge device consisting of a metal capable of stable operation at an elevated tem-

perature, a compound of a material capable in a reduced state of higher electron emission than said metal, and carbon in a quantity insufficient to deleteriously affect the strength of said material, but being capable of reducing a sufficient amount of said compound to enable said electrode to be more readily activated during use than would be the case in the absence of said carbon.

25. A cathode material for electrical discharge devices consisting largely of a metal capable of operation at an elevated temperature, a reducible compound of a material of high electron emissivity and less than about one per cent of carbon.

In witness whereof, I have hereunto set my hand this 8th day of August, 1921.

INSTRUCTIONS FOR USING

De Forest Audion Type DV-5

Filament battery voltage: 6 Volts.
Filament current: .25 Amperes.
Plate Battery Voltage for:
1. Audio Frequency Amplifier,
    (a) Transformer coupled: 90—112½ Volts.
    (b) Resistance coupled: 112½—180 Volts.
2. Radio Frequency Amplifier: 67½—135 Volts.
3. Detector in a regenerative circuit only: 12—22½ Volts.

Resistance of rheostat for operating one DV-5 tube only: 15 ohms.

Resistance of rheostat for operating two or more DV-5 tubes in parallel: 6 ohms.

When "B" battery voltages greater than 90 volts are used on audio frequency amplifiers, the following "C" battery values should be applied:

"C" Battery Voltage	"B" Battery Voltage
1½ Volts	112½ Volts
3 "	135 "
6 "	157½ "
7½ "	180 "

When using the DV-5 as a Regenerative Detector use a Grid Condenser of .00025 mfd capacity and a Grid Leak of from 5 to 10 megohms.

The DV-5 may be used in all positions, but with particular advantage:—

As a Radio Frequency Amplifier in non-oscillating R.F. circuits.

As a Detector in Regenerative Circuits using low "B" battery voltage.

As an Audio Frequency Amplifier in Resistance coupled A.F. circuits.

As an Audio Frequency Amplifier in Transformer coupled A.F. circuits where the transformers are especially designed to handle considerable amounts of power.

As an Amplifier in Reflexed positions of Reflex circuits.

CAUTION

Keep the light in this Audion as dim as possible for clear reception. Most sets contain a "volume control" by which the desired volume can be obtained at low filament voltages.

Keep this "volume control" set near "Maximum." Then regulate the filament control for best reception. This will insure maximum life from De Forest Audions.

Recharge the "A" battery when it becomes necessary to advance the rheostat.

The lowest filament voltage which can be used to give good reception is the proper voltage for operating De Forest DV-5 Audions.

The DV-5 is designed to utilize a high "B" battery voltage. Maintenance of this voltage is absolutely necessary for proper working of any set containing DV-5 Audions.

A set of "B" batteries should never be used after the voltage has fallen below 15% of their original or rated value. As soon as it becomes necessary to light the filament in DV-5 Audions brighter than usual to secure the desired volume, test the "B" batteries. CONTINUED USE OF RUN DOWN "B" BATTERIES WILL RUIN THE AUDIONS.

Never connect new "B" batteries to old or run down "B" batteries. Change the entire set when the "B" voltage gets low.

Never attempt to operate two types of De Forest Audions with the filaments in parallel and controlled from one rheostat. To do so will greatly shorten the life of all of the Audions so used.

IMPORTANT

Handle De Forest Audions carefully. The Audion is a precision instrument requiring great skill and accuracy in its manufacture. It must be handled with as much care as any delicate instrument. Never lay them down on a hard surface but first put down a pad of cloth or other soft material on which to lay them.

Never change connections in or to the set without first removing the Audions.

When taking De Forest Audions out of sockets, or putting them in, ease them into or out of the sockets.

Never change the tubes without first turning the rheostats to "off" position.

Observance of all these precautions will insure long life and continued satisfaction from De Forest DV-5 Audions.

The DV-5 should be mounted in a vertical position. The use of a cushioned support for sockets is strongly recommended.

As a regenerative detector, the grid return should be connected to the positive filament terminal as in diagram 1.

As an Audio Frequency Amplifier the grid return should be connected to the negative "A" battery terminal with the rheostat placed as shown in diagram 2. When "B" battery voltages higher than 90 volts are used, the use of a "C" battery is necessary. The connections are shown in diagram 2.

As a Radio Frequency Amplifier, the grid return should be connected as described in the particular circuit being used.

WARNING: DO NOT INCREASE FILAMENT VOLTAGE ABOVE 5 VOLTS.

This tube is manufactured under U. S. Patents: 6-26-06, 11-13-06, 1-15-07, 10-8-07, 2-18-08, 4-7-08, 9-22-08, 12-20-10, 2-18-16, 10-17-16, 4-3-17, 7-29-19, 8-29-19, 8-3-20, 9-7-20, 5-1-23, and other patents pending.

BROADCAST TO ALL AMATEUR STATIONS
ANNOUNCING THE NEW DE FOREST "H" TYPE TRANSMITTING TUBE

It will be of interest to you to know that we have developed a new power tube which is designed to meet the requirements of the Amateur and Experimental stations in their work on short wave transmission.

The distinct features of this tube are that exceptional output wattage can be obtained without breakdown. Purposely no fixed output rating is being given this tube as its efficiency and function is dependent to a large extent upon power applied, circuit arrangement and wave length.

The tube will be known as the De Forest "H" type power tube. (see enclosed circular for approximate ratings.)

Grid, plate and filament leads are brought out at widely separated places of the tube, ~~well~~ insulated and giving every reasonable assurance against high frequency flashover.

The elements are rigid - Molybdenum is employed in both grid and plate - Each tube is carefully subjected to gas, oscillation, emission, insulation resistance and voltage tests.

The tube performs remarkably well on all wave lengths especially on those of from one meter to two hundred meters.

Those of the experimental and amateur stations which have been supplied with this new oscillator report exceptionally long distance results.

We have established a very low price on this tube, namely $18.00 net, parcel post prepaid. The reason for this price is that as has always been the case with us, we desire to continue as leaders in encouraging the activities of the amateur. The tube will be sold direct to the amateur at the established price. It cannot be bought through our jobbers or dealers. At this price it is necessary to ask that when orders are sent in, the money must accompany the order.

Address your communication to Department "T", De Forest Radio Company, 120 Sherman Avenue, Jer. y City, N. J.

Yours very truly,
DE FOREST RADIO COMPANY
W. C. von Brandt
Manager, Tube Sales

Long Distance Communication

Established by means of the new

DE FOREST

"H" type Transmitting Tube

Pres

Q.S.T!

Short Wave Transmission a Success with

The New DeForest "H" Transmitting Tube

Your Success on the Lower Waves

depends upon your selection of the proper transmitting tube.

Such a transmitting tube is now produced by the DeForest Radio Company, and will be sold under the designation of the

DeForest "H" Tube

Efficient performance is obtained by the "H" tube on wave lengths of from 1 Meter to 200 *Meters*; in fact, on all wave lengths for which a circuit can be provided.

High frequency flash-over does not break down the tube as all leads are brought out at widely separated places.

High plate voltages may be used without fear of damage to any of the elements. Internal construction is rigid and the best of material is used. Both Grid and Plate are of Molybdenum.

The output ratings given below are approximate, because function and output efficiency depend largely upon the power applied, upon circuit arrangement and upon wave length.

No base is provided for this tube, in order to give it characteristics of a truly low loss oscillator.

Experiments conducted by the DeForest Laboratories indicate definitely that the new developments embodied in this "H" tube will now permit extremely long distance communication on the high frequencies.

TECHNICAL DATA

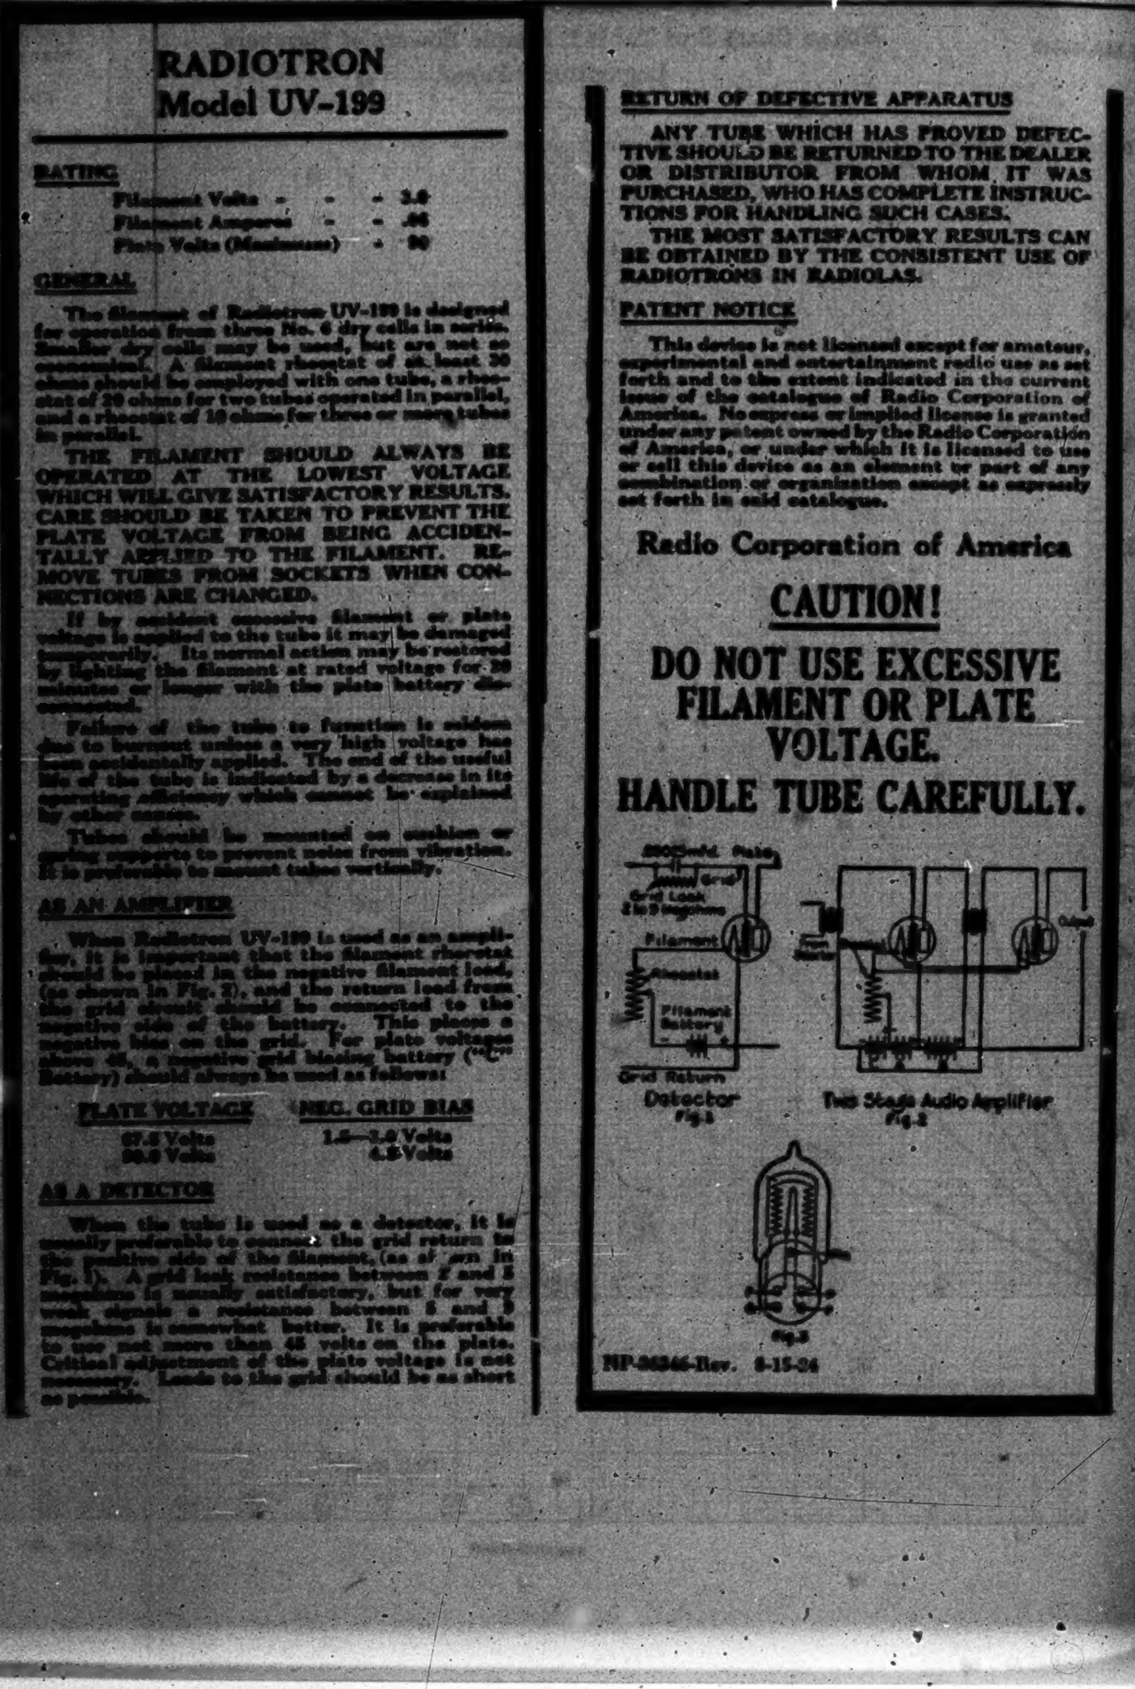
Plaintiff's UV 199 Tube.

PLAINTIFF'S EXHIBIT No. 16-A.

Data Sheet Enclosed With UV 199 Tube.



RADIOTRON
Model UV-199

RATING

Filament Volts - - -	3.0
Filament Amperes - -	.06
Plate Volts (Maximum) -	90

GENERAL

The filament of Radiotron UV-199 is designed for operation from three No. 6 dry cells in series. Smaller dry cells may be used, but are not so economical. A filament rheostat of at least 30 ohms should be employed with one tube, a rheostat of 20 ohms for two tubes operated in parallel, and a rheostat of 10 ohms for three or more tubes in parallel.

THE FILAMENT SHOULD ALWAYS BE OPERATED AT THE LOWEST VOLTAGE WHICH WILL GIVE SATISFACTORY RESULTS. CARE SHOULD BE TAKEN TO PREVENT THE PLATE VOLTAGE FROM BEING ACCIDENTALLY APPLIED TO THE FILAMENT. REMOVE TUBES FROM SOCKETS WHEN CONNECTIONS ARE CHANGED.

If by accident excessive filament or plate voltage is applied to the tube it may be damaged temporarily. Its normal action may be restored by lighting the filament at rated voltage for 20 minutes or longer with the plate battery disconnected.

Failure of the tube to function is seldom due to burnout unless a very high voltage has been accidentally applied. The end of the useful life of the tube is indicated by a decrease in its operating efficiency which cannot be explained by other causes.

Tubes should be mounted on cushion or spring supports to prevent noise from vibration. It is preferable to mount tubes vertically.

AS AN AMPLIFIER

When Radiotron UV-199 is used as an amplifier, it is important that the filament rheostat should be placed in the negative filament lead, (as shown in Fig. 2), and the return lead from the grid circuit should be connected to the negative side of the battery. This places a negative bias on the grid. For plate voltages above 45, a negative grid biasing battery ("C" Battery) should always be used as follows:

PLATE VOLTAGE	NEG. GRID BIAS
67.5 Volts	1.5—3.0 Volts
90.0 Volts	4.5 Volts

AS A DETECTOR

When the tube is used as a detector, it is usually preferable to connect the grid return to the positive side of the filament, (as shown in Fig. 1). A grid leak resistance between 2 and 5 megohms is usually satisfactory, but for very weak signals a resistance between 5 and 9 megohms is somewhat better. It is preferable to use not more than 45 volts on the plate. Critical adjustment of the plate voltage is not necessary. Leads to the grid should be as short as possible.

RETURN OF DEFECTIVE APPARATUS

ANY TUBE WHICH HAS PROVED DEFECTIVE SHOULD BE RETURNED TO THE DEALER OR DISTRIBUTOR FROM WHOM IT WAS PURCHASED, WHO HAS COMPLETE INSTRUCTIONS FOR HANDLING SUCH CASES.

THE MOST SATISFACTORY RESULTS CAN BE OBTAINED BY THE CONSISTENT USE OF RADIOTRONS IN RADIOLAS.

PATENT NOTICE

This device is not licensed except for amateur, experimental and entertainment radio use as set forth and to the extent indicated in the current issue of the catalogue of Radio Corporation of America. No express or implied license is granted under any patent owned by the Radio Corporation of America, or under which it is licensed to use or sell this device as an element or part of any combination or organization except as expressly set forth in said catalogue.

Radio Corporation of America

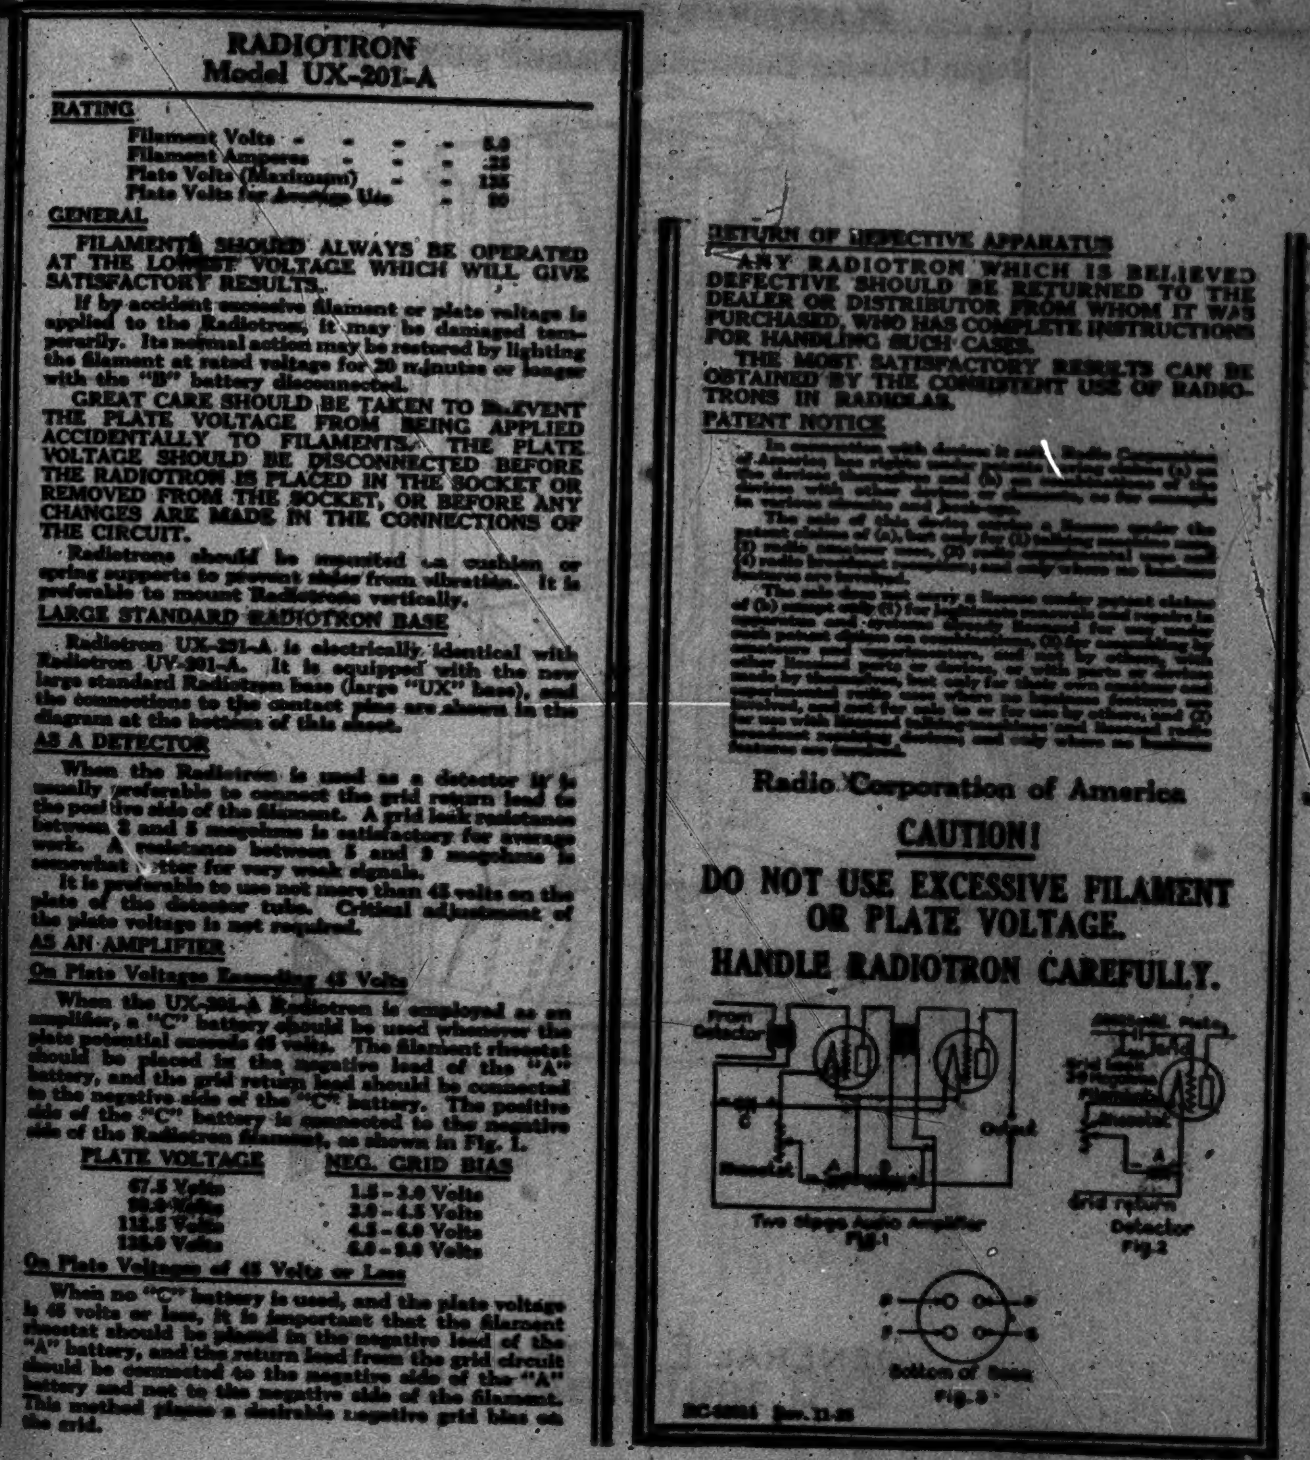
PLAINTIFF'S EXHIBIT No. 17-A

Data Sheet Enclosed With UX 201A Tube.



RADIOTRON
Model UX-201-A

RATING

Filament Volts - - - - -	5.0
Filament Amperes - - - -	.25
Plate Volts (Maximum) - -	135
Plate Volts for Average Use -	90

GENERAL

FILAMENTS SHOULD ALWAYS BE OPERATED AT THE LOWEST VOLTAGE WHICH WILL GIVE SATISFACTORY RESULTS.

If by accident excessive filament or plate voltage is applied to the Radiotron, it may be damaged temporarily. Its normal action may be restored by lighting the filament at rated voltage for 20 minutes or longer with the "B" battery disconnected.

GREAT CARE SHOULD BE TAKEN TO PREVENT THE PLATE VOLTAGE FROM BEING APPLIED ACCIDENTALLY TO FILAMENTS. THE PLATE VOLTAGE SHOULD BE DISCONNECTED BEFORE THE RADIOTRON IS PLACED IN THE SOCKET OR REMOVED FROM THE SOCKET, OR BEFORE ANY CHANGES ARE MADE IN THE CONNECTIONS OF THE CIRCUIT.

Radiotrons should be mounted on cushion or spring supports to prevent shock from vibration. It is preferable to mount Radiotrons vertically.

LARGE STANDARD RADIOTRON BASE

Radiotron UX-201-A is electrically identical with Radiotron UV-201-A. It is equipped with the new large standard Radiotron base (large "UX" base), and the connections to the contact pins are shown in the diagram at the bottom of this sheet.

AS A DETECTOR

When the Radiotron is used as a detector it is usually preferable to connect the grid return lead to the positive side of the filament. A grid leak resistance between 2 and 5 megohms is satisfactory for average work. A resistance between 5 and 9 megohms is somewhat better for very weak signals.

It is preferable to use not more than 45 volts on the plate of the detector tube. Critical adjustment of the plate voltage is not required.

AS AN AMPLIFIER

On Plate Voltages Exceeding 45 Volts

When the UX-201-A Radiotron is employed as an amplifier, a "C" battery should be used whenever the plate potential exceeds 45 volts. The filament rheostat should be placed in the negative lead of the "A" battery, and the grid return lead should be connected to the negative side of the "C" battery. The positive side of the "C" battery is connected to the negative side of the Radiotron filament, as shown in Fig. 1.

PLATE VOLTAGE	NEG. GRID BIAS
67.5 Volts	1.5 – 3.0 Volts
90.0 Volts	3.0 – 4.5 Volts
112.5 Volts	4.5 – 6.0 Volts
135.0 Volts	6.0 – 9.0 Volts

On Plate Voltages of 45 Volts or Less

When no "C" battery is used, and the plate voltage is 45 volts or less, it is important that the filament rheostat should be placed in the negative lead of the "A" battery, and the return lead from the grid circuit should be connected to the negative side of the "A" battery and not to the negative side of the filament. This method places a desirable negative grid bias on the grid.

RETURN OF DEFECTIVE APPARATUS

ANY RADIOTRON WHICH IS BELIEVED DEFECTIVE SHOULD BE RETURNED TO THE DEALER OR DISTRIBUTOR FROM WHOM IT WAS PURCHASED, WHO HAS COMPLETE INSTRUCTIONS FOR HANDLING SUCH CASES.

THE MOST SATISFACTORY RESULTS CAN BE OBTAINED BY THE CONSISTENT USE OF RADIOTRONS IN RADIOLAS.

PATENT NOTICE

In connection with devices it sells, Radio Corporation of America has rights under patents having claims (a) on the devices themselves and (b) on combinations of the devices with other devices or elements, as for example in various circuits and hook-ups.

The sale of this device carries a license under the patent claims of (a), but only for (1) talking machine uses, (2) radio amateur uses, (3) radio experimental uses and (4) radio broadcast reception; and only where no business features are involved.

The sale does not carry a license under patent claims of (b) except only (1) for legitimate renewals and repairs in apparatus and systems already licensed for use under such patent claims on combinations, (2) for assembling by amateurs and experimenters, and not by others, with other licensed parts or devices, or with parts or devices made by themselves, but only for their own amateur and experimental radio uses where no business features are involved, and not for sale to or for use by others, and (3) for use with licensed talking-machines and licensed radio broadcast receiving devices, and only where no business features are involved.

Radio Corporation of America

CAUTION!

DO NOT USE EXCESSIVE FILAMENT OR PLATE VOLTAGE.

[NOTE: FOR PLAINTIFF'S EXHIBITS NOS. 20 TO 161 INCLUSIVE, SEE INTERFERENCE RECORD]

PLAINTIFF'S EXHIBIT No. 162.

In the Court of Appeals of the District of Columbia

IRVING LANGMUIR, Appellant, vs. HAROLD D. ARNOLD.	No. 1680. Patent Appeal

OPINION OF THE COURT
(Filed June 1, 1925)

(Before MARTIN, Chief Justice, and ROBB and VAN ORSDEL, Associate Justices)

Appeal from a decision of an Assistant Commissioner of Patents in an interference proceeding awarding priority to the junior party, Arnold, and reversing concurrent decisions of the Examiner of Interferences and the Board of Examiners-in-Chief.

The invention is a thermionic tube adapted to be used as a relay in long distance telephone systems, as a detector or amplifier in wireless systems, or as a rectifier of alternating currents. The issue is expressed in thirteen counts, of which the 1st, 7th and 13th, here reproduced, will serve as examples:

> "1. A high vacuum electron discharge device comprising an envelope, an incandescent cathode and an anode, the space in said envelope being evacuated to such degree that the passage of current produces no appreciable positive ionization when the impressed voltage is as high as 200 volts."

> "7. A discharge device comprising a tube and electrodes therein one of which is adapted to emit electrons, the degree of evacuation and the relation of the parts of the device being such that the device is capable of being so operated, when volt-

> ages materially higher than ionization voltages are impressed on electrodes of the device and when the electron emission has any value such that the space current is below the saturation region at such voltage, that the line obtained by plotting the logarithms of any values of said current below the saturation region as ordinates against the logarithms of the corresponding values of said impressed voltages as abscissae is straight and continuous."
>
> "13. The method of controlling an electric current in one circuit by an electromotive force in another circuit which consists in causing said current at voltages materially above ionization voltages to pass as a discharge across a vacuous space between an electron emitting cathode and an anode, maintaining a high vacuum in said space, governing or limiting the current by a space charge effect in said space substantially unaffected by positive ionization, and superimposing the effect of said electromotive force on said space charge effect to control said current in a stable and reproducible manner."

The attitude of the junior party, appellee here, when this interference was declared, is significant. He filed a motion challenging the patentability of the issue and sought and obtained permission to take evidence in support of that motion. The result was the taking of voluminous testimony by the parties on this issue, which by stipulation is in the record here. The Law Examiner, to whom this question was initially referred, sustained the patentability of the issue and his decision is controlling here. We therefore start our inquiry in this appeal with the established fact that, so far as this proceeding is concerned, the issue is patentable; in other words, that something more than mere mechanical skill was involved in the result achieved.

The Examiner of Interferences, in an exhaustive opinion, awarded priority to the senior party, Langmuir. The Board, on appeal, directed attention to the fact that, structurally considered, the tubes of both parties outwardly are substantially identical with the Fleming valve and the DeForest audion of the prior art; that the invention has been referred to as a "thing compact of glass and metal". The Board then pointed out that this definition, although correct as far as it goes, is inadequate because it applies equally well to the prior art devices, and that to this definition should be added the qualification that the device "operates with a *pure* electronic discharge above the voltage of positive ionization and below saturation", and proceeded: "But how is one to know whether the discharge is purely electronic? In other words, how is one to know whether a tube embodies merely the prior art devices or the invention of the issue? * * * For example, count 1 specifies that the envelope of the tube is evacuated to such a degree that the passage of current produces no appreciable positive ionization when the impressed voltage is as high as 200 volts. Thus the count distinguishes from the prior art, not by features of structure, but by a characteristic which is manifest while the device is operating at or above a certain voltage."

Later in its decision the Board suggested that the question to be determined was, who of the parties "first knowingly and understandingly conceived and produced such a tube"; that Arnold, the junior party, did not claim to have conceived the invention prior to November 1, 1912, or to have reduced it to practice prior to the 29th of that month; that Langmuir, on the other hand, alleged conception, disclosure, sketches, written description and successful operation prior to September 1, 1912, followed in November of that year by the successful operation of other devices embodying the invention. The Board then carefully reviewed the testimony in support of Langmuir's contentions and found that he had conceived the invention of counts 1 to 11, inclusive, as early as September 1, 1912, and had reduced the same to practice by November 19th of the same year; that, as to counts 12 and 13, Langmuir had conceived prior to April 8, 1913, and had reduced to practice by April 15th of that year; that Arnold conceived and reduced to practice the invention of all of the counts except counts 1 and 11 on April 25, 1913, and that counts 1 and 11 were not reduced to practice until after Langmuir's filing date.

The attitude of the Assistant Commissioner toward the case was that of the junior party upon the declaration of the interference, namely, that the patentability of the issue was doubtful. He says: "The line between the prior art and the issue is attenuated and if there is patentability, it must be as set out in the decision of the Law Examiner on the motion, and I do not understand either party to attack that decision here. Arnold alleges that when he made the invention, he thought he was following the prior art and not producing something patentable, and an undercurrent of that attitude seems to tinge his whole case. This is why he filed so late." Proceeding from that postulate, the Assistant Commissioner has accepted as controlling on the question of conception and reduction to practice, on behalf of Arnold, testimony of a vague and general character and which failed to satisfy the lower tribunals, as it also has failed to satisfy us. The decisions of those tribunals are so clear and satisfying that we are content to rest our opinion upon the reasoning there given.

It results that the decision is reversed and priority awarded Langmuir.

Reversed.

CHAS. H. ROBB,
Associate Justice.

Patent Case 17605 Feb 7/13

Schenectady, N. Y. Feb. 5, 1913.

Miss H. Orford,
Patent Department.

Dear Miss Orford:

As a matter of record of conversation with Mr. Hawkins and Dr. Coolidge on Jan. 9th, please docket a case for me on the use of an X-ray tube as an amplifier for high frequency current for wireless telegraphy. In the incandescent rectifier which is sometimes used as a detector, relay action is obtained by introducing the controlling potential on a grate grid which is placed in the flow of the radiating energy. The controlling potential has the effect of starting and stopping the flow and this principle may be app lied on a large scale as an amplifier for sending purposes.

I have a patent used sometime ago covering broadly the use of this principle in combination with telephone for sending wireless telephone messages.

This particular construction of the X-ray tube suggested to me the possible advantages of deflection, rather than stopping the flow of energy by providing two targets and deflecting the flow of energy from the antenna circuit to the local circuit. The deflection may be produced either by electro-magnet which is controlled by the telephone or by an electrostatic potential.

A. Allen Orford

DIV [illegible]

NOV [illegible] 10

To the Commissioner of Patents:

Your petitioner HAROLD D. ARNOLD

citizen of the United States, residing at East Orange in the County of Essex and State of New Jersey, whose post-office address is 140 South Munn Avenue, East Orange, New Jersey, prays that Letters Patent may be granted to him for the improvement in MANUFACTURE OF VACUUM TUBE DEVICES, set forth in the annexed specification; and he hereby appoints DE WITT C. TANNER (Reg. No. 4325) and JOHN G. ROBERTS (Reg. No. 9084) of No. 463 West Street, New York, New York, severally, his attorneys, with full power of substitution and revocation, to prosecute said application, to make alterations and amendments therein, to receive the patent, and to transact all business in the Patent Office connected therewith; and requests that communications from the Patent Office in connection with this application be addressed to said JOHN G. ROBERTS.

Harold D. Arnold

Case 15

TO ALL WHOM IT MAY CONCERN:

Be it known that I, HAROLD DE FOREST ARNOLD, a citizen of the United States, residing at East Orange, in the County of Essex and State of New Jersey, have invented certain new and useful improvements in the MANUFACTURE OF VACUUM-TUBE DEVICES, of which the following is a full, clear, concise, and exact description.

This invention relates to the manufacture of vacuum tube devices, and more particularly it relates to a method of exhausting air and other gases and vapors from the glass bulbs or containers which enclose the electrode elements of thermionic repeaters, such as audions, and similar devices in which extremely high vacua are desired.

Its objects are an effectively complete elimination of the gases occluded by the walls of the containing vessel, and by the electrode elements and other metallic surfaces enclosed therein; a removal of such gases or any other gases from the containing vessel, and a resulting product characterized by stability and uniformity of operation.

To these ends this invention provides for the attachment of the vessel to be exhausted to any suitable vacuum pump and for the application of heat to the exterior of such vessel during the process of evacuation. It further provides for the heating of one or more of the enclosed electrodes by the passage of an electric current therethrough, and for the production in said vessel of an electron discharge which may be made to bombard and heat another electrode through the application of a suitable potential difference between the said electrode and the source of said discharge.

A more complete understanding of the method of this invention will be obtained by consideration of the attached drawing, which illustrates an apparatus arrangement suitable for producing the high vacua desired in thermionic devices of the audion type. It will, of course, be appreciated that the method herein disclosed is equally applicable to the production of high vacua in any device having an electrode or electrodes capable of producing an electron discharge.

In the drawing, a plurality of thermionic repeater elements 2, each having the customary filamentary cathode 3, grid 4 and anode 5, are enclosed in an oven 6 which may be electrically heated by a resistance element 7 connected to a suitable source of current 8. The glass containing-vessels 9 of the elements 2 have tubular extensions 10 connected to a main tube 11 leading to an exhaust apparatus 12, such, for example, as a Gaede molecular pump, connected to a source of motive power 13. The terminals of the electrode elements 3, 4 and 5 are brought out through suitable apertures 14 in one of the walls of the oven 6, so as to be readily available for test purposes and for the application of any desired electromotive force. A suitable number of windows 15 are provided in the front of the oven 6 so that the appearance of the tubes 2 being exhausted may be observed during the process. The filaments 3 are connected in series with a source of current 16 and a variable resistance 17. The process of exhausting the vessels 9 is as follows: The pump 12 is started and the temperature of the oven 6 is gradually raised until it has reached approximately 350° C. The purpose of this heating is to drive out the gases occluded by the walls of the vessel 9. After the temperature of the oven has risen to about 250° C., the filaments 3 are brought to incandescence by current supplied from the source 16, which current is raised to a value approximately 10% greater than the current normally to be used in the operation of the completed device. A potential difference is thereupon successively applied to the terminals of the electrodes 4 and 5 by means of a test clip 20 connected through the potentiometer 21 to a direct current source 22 of about 220 volts output. The filament 3 being

connected to the negative terminal of the source 22 as shown, and the test clip 20 being connected to the positive terminal of the source 22, there will result an electron discharge from the cathode 3 to the electrode 4 or 5, to which the test clip 20 is temporarily connected. This potential difference is made sufficiently high, through adjustment of the potentiometer 21, to cause an electron discharge of sufficient volume to heat the electrode 4, to which the test clip 20 is attached, even to incandescence, which heating is effective to drive out any gases which may be occluded by said electrode.

The electron discharge, which passes from the cathode 3 to either electrode 4 or 5 when a potential difference is established therebetween, partially ionises whatever gas may be in its path. When gas in sufficient quantity is thus ionised, there will result a blue glow in part or all of the vessel 9, which may readily be observed through one of the windows 15. The intensity of this blue glow depends upon the amount of gas present and upon the current and potential difference impressed between the cathode 3 and electrode 5. For a given current and potential difference therefore, this blue glow will gradually become fainter as the gas within the vessel becomes more attenuated, until the glow finally disappears.

A visible indication of the sufficiency of evacuation is therefore available, and, for example, in exhausting the bulbs of thermionic repeaters, such as are employed in telephone work, it has been found that a sufficiently high vacuum has been obtained if the blue glow no longer appears, when approximately 175 volts potential difference is impressed between the cathode 3 and the anode 5. When this point has been reached, the tubes are allowed to cool gradually and are sealed off of the pump 12 and given an aging run, which consists in applying the normal heating current to the filaments 3 and impressing the customary operating potential difference between the cathode 3 and anode 5. It has been found that after an aging run of from fifteen to twenty hours duration, for example, the repeaters have reached a stable condition and may be relied upon to give constant and uniform results.

In case the thermionic device to be exhausted is equipped with a grid 4 of very fine mesh, as in the case of a repeater designed for voltage amplification, it may be difficult to obtain a current to the electrode 5 sufficient to heat it properly. In such an event, it has been found desirable to apply an additional positive potential from a source 23, for example of perhaps 60 volts output, to the grid electrode 4 at the same time that the positive potential from source 22 is being applied to the anode 5. This increases the flow of electrons to the anode 5, and as some current will also flow between the filament 3 and grid 4, the voltages may be adjusted so as to heat both electrodes 4 and 5 at the same time.

With some tubes the early part of the process may be accelerated by applying to both the grid electrode 4 and the anode 5 the same large potential as that which later in the process is applied to the anode only.

WHAT IS CLAIMED IS:

Ins A

1. The method of producing a high vacuum in a thermionic discharge tube, which consists in establishing an electron discharge within said tube during the process of evacuation and causing said discharge to bombard an electrode element within said tube, thereby heating said electrode and driving out the gases occluded thereby.

Sub. C'

Insert B'

Per B

1ª ~~2.~~ The method of producing a high vacuum in a thermionic discharge tube containing a plurality of electrodes, which Ⓑ' ~~consists in~~ heating one of said electrodes to incandescence and simultaneously establishing an electron discharge between said electrode and a second electrode, whereby said second electrode is heated and its occluded gases are expelled.

Ins A

3. The method of producing a high vacuum in a thermionic discharge tube, which consists in applying heat to the exterior of said tube during the process of evacuation and in establishing an electron discharge within said tube and causing said discharge to bombard and heat an electrode within said tube and to drive out the gases occluded thereby.

Per C

Ins A

Insert C'

2. ~~4.~~ The method of producing a high vacuum in a thermionic discharge tube containing three electrodes, ~~in heating one of said electrodes to incandescence~~ which consists, in establishing an electron discharge between ~~two of said electrodes whereby one of said electrodes is~~ C' heated during the process of evacuation, and in assisting the passage of said discharge by means of a potential differ- third electrode.

Ins A

3ª ~~5.~~ The method of producing a high vacuum in a thermionic discharge tube containing three electrodes ~~in heating one of said electrodes to incandescence~~ which consists in establishing an electron discharge between ~~one of~~ said electrodes and the other two electrodes during the process of evacuation, whereby said two electrodes are heated by bombardment and their occluded gases are driven off.

Serial No. 62,259
Filed Nov. 19, 1915

Manufacture of Vacuum Tube Devices.

COMMISSIONER OF PATENTS,
Washington, D. C.

Sir:-

This amendment is in response to the Office action of April 25, 1916. Please amend the application as follows:

✓ Cancel claims 1 and 3 and renumber the remaining claims as 1, 2 and 3:

✓ In present claim 2, line 3, after "consists" insert --in heating one of said electrodes to incandescence,--; cancel line 4, and substitute the following: --said heated electrode and a second one of said electrodes whereby said second electrode is--.

c

✓ Present claim 3, line 3, after "consists" insert --in heating one of said electrodes to incandescence,--; line 4, cancel "one of said electrodes" and insert --said electrode--.

REMARKS

Rejection of present claim 1 upon the patent to Snook is thought to be an error, for Snook does not use an electrode which can be heated to incandescence in the manner explained in this application. Snook shows two cold electrodes k and a, one of which may be heated by bombardment to a certain degree, but certainly not to such a temperature as is understood by the term "incandescence". Applicant has in mind and clearly explains in his application that one electrode is to be heated to incandescence by an electric current and as a result of this high heating will give off its occluded gas and at the same time will constitute a source of electrons which may then be driven to a second electrode to heat and bombard this second electrode in such a manner as to drive off its occluded gas. No such process is intimated or is even possible in Snook's arrangement.

It is thought that present claim 2 is allowable in the form in which it was submitted, but in order to more fully distinguish from the patent to Snook, the claim has been limited by including the step of heating one of the electrodes to incandescence. It is to be emphasized that this claim sets forth a process particularly adapted for use in a vacuum discharge tube where one electrode may act as a serious barrier to the establishment of a fairly large electron stream to a third electrode. The claim points out that the step for overcoming the difficulty consists in applying a potential difference between the source of discharge, which is now defined as the incandescent electrode and thereby establishing an electron stream or discharge between said incandescent electrode and the impeding electrode. With this explanation as to this claim 2, it is thought that the calim will be found allowable.

Claim 3 has been amended to distinguish from Snook by inserting the step of heating one of the electrodes to incandescence, and as pointed out in connection with claim 1, this electrode is then caused to give up its occluded gas and at the same time to become an electron source, making it possible to establibh an electron discharge between said electrode and the other two electrodes.

(Serial No. 62,259)

An affidavit executed by Harold D. Arnold is attached hereto overcoming the British patent 15,788 of 1914 as a reference so far as these claims are concerned. An affidavit executed by Russell F. Trimble is also attached, verifying the statements made by Arnold in his affidavit.

Allowance of the application, as now amended, is respectfully requested.

Respectfully,

HAROLD DeFOREST ARNOLD,

By J G Roberts

RUSSELL FAY TRIMBLE, being duly sworn, deposes and says:

That he is of legal age and a citizen of the United States; that he has been in the employ of the Western Electric Company, Incorporated, since and prior to January 1913; that since said date of January 1913, he has been in charge of a large part of the work relating to the evacuation of vacuum tube devices; that prior to October 1, 1915 it was a usual and common expedient in the laboratories of the Western Electric Company, when evacuating such devices, to have one electrode (in the form of a filament) heated to incandescence and to have a second electrode connected to said first electrode by means of a source of potential, the second electrode being connected to the positive terminal of the source, whereby an electron discharge was caused to flow from said filament to said second electrode. The purpose of this was to bombard and heat the second electrode in such a manner and to such an extent as to cause it to give off occluded gases. This method of evacuating vacuum tubes was followed by myself and my assistants, and was done at the suggestion and under the instructions of Harold D Arnold, under whose direction I was working.

WASHINGTON June 6, 1917.

Mr. John G. Roberts,
465 West Street,
New York, N. Y.

Please find below a communication from the EXAMINER in charge of the application of

H. D. Arnold, S. No. 62,259, filed Nov. 18, 1915,

Manufacture of Vacuum Tube Devices.

Thomas Ewing
Commissioner of Patents.

This action is in response to amendment filed Apr. 24, 1917.

Claim 1 is rejected as not setting forth a method for producing a vacuum as the operation set out is insufficient to produce a vacuum. Further, the operation set out is a step described in the evacuating process described in patent No. 1,166,792, Enock, of record. See page 4, lines 31 to 60 of the reference. This claim is accordingly rejected on patent No. 1,166,792, cited.

Claims 2 and 3 appear to be allowable.

B

Sir:

In reply to the Office action of June 8, 1917, please amend as follows:

✓ Claim 1, line 3, cancel "consists in" and substitute --comprises performing the following steps during the process of evacuation, i. e.--; line 4, after "and" insert --simultaneously--.

B¹ Per C ✓

Add the following claims:

B² Per C

--4. The method of producing a high vacuum in a thermionic discharge tube having a filamentary cathode which consists, during the process of evacuation, in passing an electric current through said cathode to heat the same independently of electron bombardment and in heating another electrode in said tube by a space current between said cathode and said electrode.

5. The method of producing a high vacuum in a thermionic discharge tube having a cathode and an auxiliary electrode which consists, during the process of evacuation, in passing an

(Serial No. 62,259)

~~electric current through said cathode to heat the same independently of electron bombardment and in heating said auxiliary electrode by bombardment from said cathode.--~~

REMARKS

Claim 1 has been amended to define a method for producing a vacuum and this has been done in terms which differentiate from the references of record by specifying that one of the electrodes is heated to incandescence and that simultaneously an electron discharge is established between said electrode and a second electrode.

It is thought that claims 4 and 5 should be allowed as the patent to Snook does not disclose a cathode which is heated independently of bombardment by an electric current passing therethrough. In applicant's case two or more electrodes may be kept hot, while the tube is pumped out, one being heated by bombardment and the other being heated independently of bombardment. This individual control of the heating of the electrodes appears novel with applicant and it is submitted that the claims 4 and 5 should be allowed.

Reconsideration and allowance are therefore respectfully requested.

Respectfully,

HAROLD DeFOREST ARNOLD,

8 C

UNITED STATES PATENT OFFICE.

Division 16 Room 112

In re application of

Harold DeForest Arnold

C

Serial No. 62,259

Filed November 18, 1915

Subject

Manufacture of Vacuum Tube Devices

THE COMMISSIONER OF PATENTS,
Washington, D. C.

Sir:

In reply to the Office action of June 18, 1918, please amend the above entitled application by cancelling all the claims and substituting therefor the following:-

41. The method of producing a high vacuum in a thermionic discharge tube containing three electrodes, which comprises heating one of said electrodes and establishing an electron discharge between said heated electrode and a second one of said electrodes, whereby said second electrode is heated during the process of evacuation, and in assisting the passage of said discharge by means of a potential difference applied between the source of said discharge and the third electrode.

// C'

2. The method of producing a high vacuum in a thermionic discharge tube containing three electrodes, which comprises heating one of said electrodes to cause it to emit

(Serial No. 62,259)

electrons, in establishing an electron discharge between said heated electrode and the other two electrodes during the process of evacuation, whereby said two electrodes are heated by bombardment and their occluded gases are driven off.

3. The method of evacuating a vacuum tube having cathode, anode and grid electrodes, which comprises energising said cathode to cause it to emit electrons, in establishing an electron discharge between said cathode and said other electrodes during the evacuation, and in maintaining said grid at a potential different from that of said cathode during said discharge.

4. The method of evacuating a vacuum tube having cathode, anode and grid electrodes, which comprises energising said cathode to cause it to emit electrons, and in maintaining said grid and anode at a positive potential with respect to that of said cathode during evacuation.

REMARKS

By reason of the amendments to allowed claims 2 and 3, these have been rewritten, and in their present form, as claims 1 and 2, differ but slightly from the form in which they were allowed. The principal difference is that the limitation as to heating one of the electrodes to incandescence has been

(Serial No. 62,259)

broadened to state that the electrode is heated, without regard as to whether this is to the point of incandescence or not. It is thought that these claims will still be allowable.

Claims 3 and 4, added by this amendment, are specific to the type of tubes which is to be evacuated, and to the potentials which are applied between the electrodes during evacuation.

Claim 4 is more specific than any of the others in that it recites that the grid is maintained at a potential which is positive with respect to the cathode during the evacuation.

This case is now believed to be in condition for allowance.

Respectfully,

HAROLD DeFOREST ARNOLD,

By WGRoberts
Attorney

Sir: Your APPLICATION for a patent for an IMPROVEMENT in

Manufacture of Vacuum Tube Devices

filed Nov. 18, 1915 , has been examined and ALLOWED.

The final fee, TWENTY DOLLARS, must be paid not later than SIX MONTHS from the date of this present notice of allowance. If the final fee be not paid within that period, the patent on this application will be withheld, unless renewed with an additional fee of $15, under the provisions of Section 4897, Revised Statutes.

The office delivers patents upon the day of their date, and on which their term begins to run. The printing, photolithographing, and engrossing of the several patent parts, preparatory to final signing and sealing, will require about four weeks, and such work will not be undertaken until after payment of the necessary fee.

When you send the final fee you will also send, DISTINCTLY AND PLAINLY WRITTEN, the name of the INVENTOR, TITLE OF INVENTION, AND SERIAL NUMBER AS ABOVE GIVEN, DATE OF ALLOWANCE (which is the date of this circular), DATE OF FILING, and, if assigned, the NAMES OF THE ASSIGNEES.

If you desire to have the patent issue to ASSIGNEES, an assignment containing a REQUEST to that effect, together with the FEE for recording the same, must be filed in this office on or before the date of payment of final fee.

After issue of the patent uncertified copies of the drawings and specifications may be purchased at the price of FIVE CENTS EACH. The money should accompany the order. Postage stamps will not be received.

Final fees will NOT be received from other than the applicant, his assignee or attorney, or a party in interest as shown by the records of the Patent Office.

Respectfully,

James T. Newton
Commissioner of Patents.

UNCERTIFIED CHECKS WILL NOT BE ACCEPTED.

Mr. John G. Roberts,
#920 Broadway,
New York, N. Y.

full pat ordered

UNITED STATES PATENT OFFICE.

HAROLD D. ARNOLD, OF EAST ORANGE, NEW JERSEY, ASSIGNOR, BY MESNE ASSIGNMENTS, TO WESTERN ELECTRIC COMPANY, INCORPORATED, A CORPORATION OF NEW YORK.

MANUFACTURE OF VACUUM-TUBE DEVICES.

1,297,309. Specification of Letters Patent. **Patented Mar. 18, 1919.**

Application filed November 18, 1915. Serial No. [illegible].

To all whom it may concern:

Be it known that I, Harold De Forest Arnold, a citizen of the United States, residing at East Orange, in the county of Essex and State of New Jersey, have invented certain new and useful Improvements in the Manufacture of Vacuum-Tube Devices, of which the following is a full, clear, concise, and exact description.

This invention relates to the manufacture of vacuum tube devices, and more particularly it relates to a method of exhausting air and other gases and vapors from the glass bulbs or containers which inclose the electrode elements of thermionic repeaters, such as audions, and similar devices in which extremely high vacua are desired.

Its objects are an effectively complete elimination of the gases occluded by the walls of the containing vessel, and by the electrode elements and other metallic surfaces inclosed therein, a removal of such gases or any other gases from the containing vessel, and a resulting product characterized by stability and uniformity of operation.

To these ends this invention provides for the attachment of the vessel to be exhausted to any suitable vacuum pump and for the application of heat to the exterior of such vessel during the process of evacuation. It further provides for the heating of one or more of the inclosed electrodes by the passage of an electric current therethrough, and for the production in said vessel of an electron discharge which may be made to bombard and heat another electrode through the application of a suitable potential difference between the said electrode and the source of said discharge.

A more complete understanding of the method of this invention will be obtained by consideration of the attached drawing, which illustrates an apparatus arrangement suitable for producing the high vacua desired in thermionic devices of the audion type. It will, of course, be appreciated that the method herein disclosed is equally applicable to the production of high vacua in any device having an electrode or electrodes capable of producing an electron discharge.

In the drawing, a plurality of thermionic repeater elements 2, each having the customary filamentary cathode 3, grid 4 and anode 5, are inclosed in an oven 6 which may be electrically heated by a resistance element 7 connected to a suitable source of current 8. The glass containing-vessels 9 of the elements 2 have tubular extensions 10 connected to a main tube 11 leading to an exhaust apparatus 12, such, for example, as a Gaede molecular pump, connected to a source of motive power 13. The terminals of the electrode elements 3, 4 and 5 are brought out through suitable apertures 14 in one of the walls of the oven 6, so as to be readily available for test purposes and for the application of any desired electromotive force. A suitable number of windows 15 are provided in the front of the oven 6 so that the appearance of the tubes 2 being exhausted may be observed during the process. The filaments 3 are connected in series with a source of current 16 and a variable resistance 17. The process of exhausting the vessels 9 is as follows: The pump 12 is started and the temperature of the oven 6 is gradually raised until it has reached approximately 350° C. The purpose of this heating is to drive out the gases occluded by the walls of the vessel 9. After the temperature of the oven has risen to about 250° C., the filaments 3 are brought to incandescence by current supplied from the source 16, which current is raised to a value approximately 10% greater than the current normally to be used in the operation of the completed device. A potential difference is thereupon successively applied to the terminals of the electrodes 4 and 5 by means of a test clip 20 connected through the potentiometer 21 to a direct current source 22 of about 220 volts output. The filament 3 being connected to the negative terminal of the source 22 as shown, and the test clip 20 being connected to the positive terminal of the source 22, there will result an electron discharge from the cathode 3 to the electrode 4 or 5, to which the test clip 20 is temporarily connected. This potential difference is made sufficiently high, through adjustment of the potentiometer 21, to cause an electron discharge of sufficient volume to heat the electrode, to which the test clip 20 is attached, even to incandescence, which heating is effective to drive out any gases which may be occluded by said electrode.

The electron discharge, which passes from the cathode 3 to either electrode 4 or 5 when a potential difference is established there-between, partially ionizes whatever gas may be in its path. When gas in sufficient quantity is thus ionized, there will result a blue glow in part or all of the vessel 9, which may readily be observed through one of the windows 15. The intensity of this blue glow depends upon the amount of gas present and upon the current and potential difference impressed between the cathode 3 and electrode 5. For a given current and potential difference therefore, this blue glow will gradually become fainter as the gas within the vessel becomes more attenuated, until the glow finally disappears.

A visible indication of the sufficiency of evacuation is therefore available, and, for example in exhausting the bulbs of thermionic repeaters, such as are employed in telephone work, it has been found that a sufficiently high vacuum has been obtained if the blue glow no longer appears, when approximately 175 volts potential difference is impressed between the cathode 3 and the anode 5. When this point has been reached, the tubes are allowed to cool gradually and are sealed off of the pump 12 and given an aging run, which consists in applying the normal heating current to the filaments 3 and impressing the customary operating potential difference between the cathode 3 and anode 5. It has been found that after an aging run of from fifteen to twenty hours duration, for example, the repeaters have reached a stable condition and may be relied upon to give constant and uniform results.

In case the thermionic device to be exhausted is equipped with a grid 4 of very fine mesh, as in the case of a repeater designed for voltage amplification, it may be difficult to obtain a current to the electrode 5 sufficient to heat it properly. In such an event, it has been found desirable to apply an additional positive potential from a source 28, for example of perhaps 60 volts output, to the grid electrode 4 at the same time that the positive potential from source 22 is being applied to the anode 5. This increases the flow of electrons to the anode 5, and as some current will also flow between the filament 3 and grid 4, the voltages may be adjusted so as to heat both electrodes 4 and 5 at the same time.

With some tubes the early part of the process may be accelerated by applying to both the grid electrode 4 and the anode 5 the same large potential as that which later in the process is applied to the anode only.

What is claimed is:

1. The method of producing a high vacuum in a thermionic discharge tube containing three electrodes, which comprises heating one of said electrodes and establishing an electron discharge between said heated electrode and a second one of said electrodes, whereby said second electrode is heated during the process of evacuation, and in assisting the passage of said discharge by means of a potential difference applied between the source of said discharge and the third electrode.

2. The method of producing a high vacuum in a thermionic discharge tube containing three electrodes, which comprises heating one of said electrodes to cause it to emit electrons, in establishing an electron discharge between said heated electrode and the other two electrodes during the process of evacuation, whereby said two electrodes are heated by bombardment and their occluded gases are driven off.

3. The method of evacuating a vacuum tube having cathode, anode and grid electrodes, which comprises energizing said cathode to cause it to emit electrons, in establishing an electron discharge between said cathode and said other electrodes during the evacuation, and in maintaining said grid at a potential different from that of said cathode during said discharge.

4. The method of evacuating a vacuum tube having cathode, anode and grid electrodes, which comprises energizing said cathode to cause it to emit electrons, and in maintaining said grid and anode at a positive potential with respect to that of said cathode during evacuation.

In witness whereof, I hereunto subscribe my name this fifteenth day of November, A. D. 1915.

HAROLD D. ARNOLD.

PLAINTIFF'S EXHIBIT No. 171.

White Note Book No. 452.

Mon. Feb. 10 '13

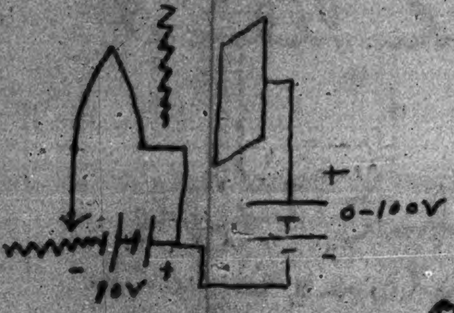
Cleaned up a quantity of mercury for Dr. Story. Air blown thru it for a number of hours.

Have decided that trouble with vacuum system is with gage column so will take it down and have a new pipe section put in and give whole a good cleaning

Spent afternoon in conversation with Dr Langmuir in regard to some experiments I am to try with the De Forest audion.

Thurs. Feb. 13 '13

assembled apparatus and made some tests on the De Forest Audion.



Mc Kay and Orange calibrated the audion filament. current temp. relation given on C.S.W. 20.

Fri Feb 14 13
to
Tues Feb 25 '13

away from lab on account illness.

Small rotary converter for vacuum gage has been fitted with steel rings and metite brushes.
It runs much smoother and should last a long while.

Thurs Mar 13 to Sat Mar 15
Completed vacuum system and exhausted an all tungsten audion.
Treatment given on R.S.W.77

Filament color matched by Orange and Mackay:
at 1.025 amps and 4.05V Temp was 2452°C Then from curves of ideal filament current-temperature curve drawn as on C.S.W.25.

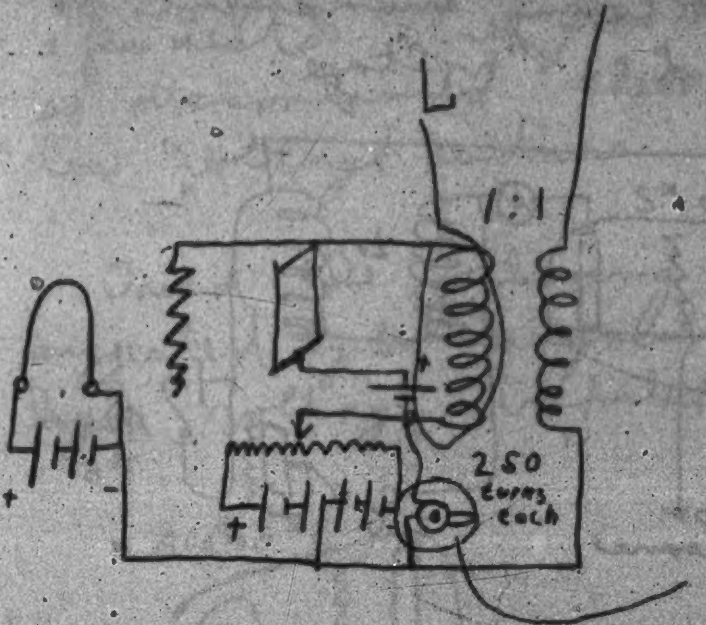
lines at very low plate voltages and high + grid voltages the curves are distorted due to fact that grid current is large in comparison with plate current

In both these sets of tests filament kept at 1.05 amps 2480°C which is above saturation on all voltage up to about 200.

From data of these two tests drew curves showing relation between grid E.M.F. and plate E.M.F. these are straight lines as long as plate current is large in comparison to grid current. These curves drawn for different currents.

In commencing tests for the day it was necessary to run filaments for quite a time to get results consistent with previous day's results. at first results were 5 to 10% high.

Tried to use # 2 as a wireless receiver using a buzzer for sender. Could get no results.

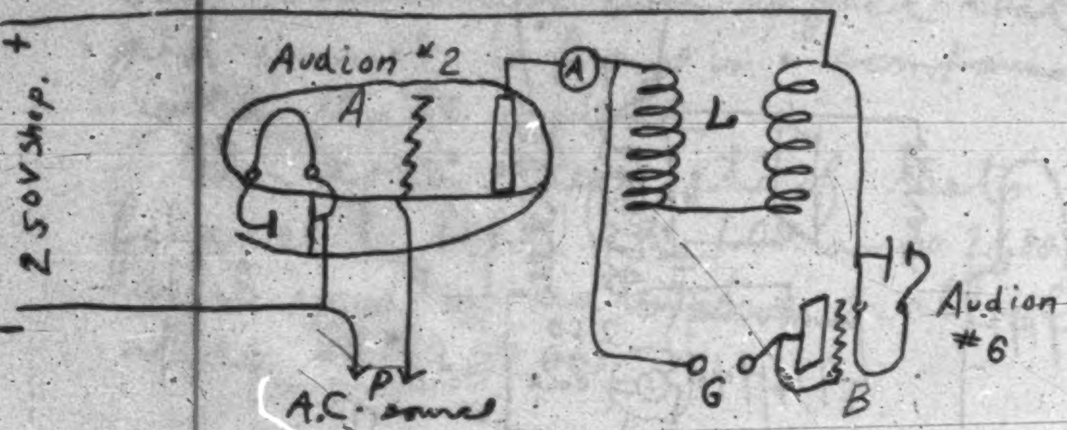


When filament is at about 1 amp a low pitch sort of rattling is heard as filament temperature is raised this raises in pitch till at about 1.3 amps it is a sort of squeal. Magnetic lines of force have the same pitch raising effect when ~~[illegible]~~ parallel to filament.

There is also ~~a~~ decided microphone effect.

Dr Langmuir suggested a D.C. transformer.

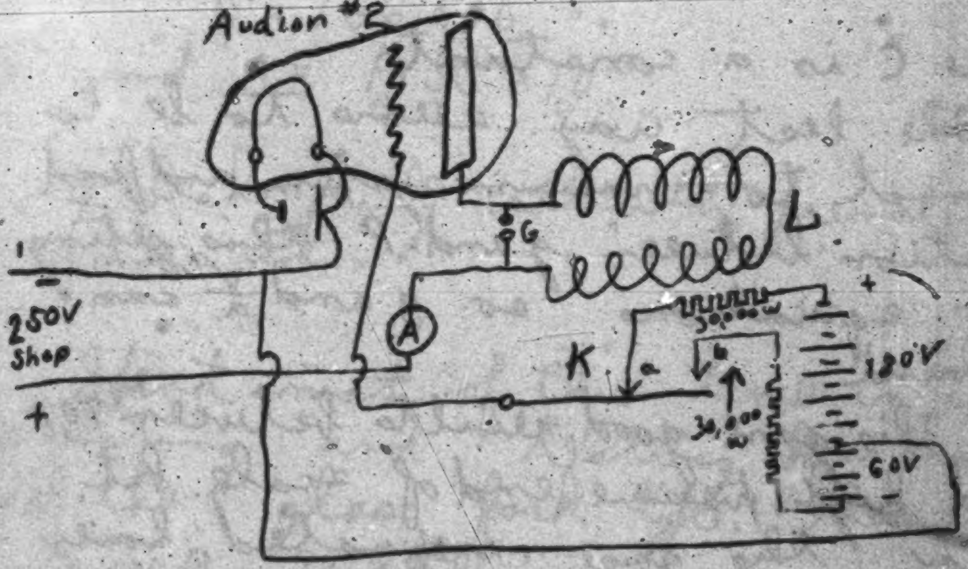
8/9/13 Used the following arrangement to step up d.c. voltage.



L is an inductance consisting of the primaries of two 200 watt 6600/100 V pot. transformers connected in series. Various A.C. sources were tried 40 ~ shop at 25 V and a special 100 ~ alternator at about 30 V

The idea being to charge up the inductance while the grid of #2 is + the E.C. doing this then in next part of cycle when grid is − the E.C. is suddenly shut off, thus allowing the coil L to discharge across gaps G Audion #6 being used as a rectifier. The higher voltage thus obtained would just about jump the smallest gap we could arrange so potential was probably about 350-400 Volt. after a few tests blue glow began to appear so discontinued these tests on these low voltage audions.

Tried the following arrangement suggested by Dr Langmuir to get single high voltage impulses



Audion #2
K
G
L
−
250V
Shop
+
A
+
30,000 ω
K
a
b
30,000 ω
180V
60V
−

The key K being used to change the sign of the grid potential very suddenly Sparks of 0.3 mm could be produced from the 250V shop.
About 25 mil-amps was passed thru L when grid was +
The high resistances were used

Calibrated another gage of the Moore type for Mr Perkins. Tried it by volume and diam. measurement but unsatisfactory

We know that relation should approximately be

$$C + g = \frac{pV}{ag} \quad \text{see pg 40}$$

where C is a constant

The best way seems to be to connect to a vacuum system and find relation between g and P, thus getting two equations so g and $\frac{V}{a}$ can be found

This gave good results between 70μ and high pressure end of scale but below this gage indicated lower pressure than equation ~~good~~ gave.

Wired up a 10K.V.A. 40,000V transformer with regulator (induction) and resistance in secondary, to be used on high voltage audion relays ect.

April 28 to May 10

Made some tests on audion #2 to get total currents obtained from filament. See RSW79.

Tried to find Q and A for this filament

It is a 2.7 mil, 14.05 mm long area
∴ = 3.03 mm^2

Q = 166,500

and A = 19.55×10^{15}

Q checks fairly well with previous results A does not.

Spent most of this time in constructing and testing four audions of the glass fork type. These are Nos 6, 7, 8, 9.

Construction data given on pgs 48, 54, 55.

Principle construction troubles were:

Winding of first grid, this overcome by practice and more careful handling of wire. Breaking of fork due

L = .0000592 henrys

For this coil the field at any point along the axis as relative to the field in plane of coil is given on C.S.W. 45 Here inverted values of relative field strength are plotted against distance along axis from plane of coil. For instance at 100 cm along axis field is only $\frac{1}{133}$ of its value at center of coil

Then tested out Mr. Alexanderson theory of geometrical tuning using two audions in series. The results of this test are described in a report. Particulars given on RSW 100-103

Evidently this feature is little effected by geometrical construction

Dr. Langmuir thinks this is due to fact that electrons leave filament at different velocities according to Maxwells distribution law so that a certain E.M.F. range is necessary to cover this range of velocities

Tried slipping audion #2 into a solenoid, capable of giving quite a powerful field.

Under certain conditions noted RSW98 the grid Eg vs E.C. curve took on form shown on CSW50. Having a sharp discontinuity, in all cases the magnetic lines parallel to the filament caused decrease in E.C. and if field was strong enough entire stoppage of it

This flat portion may be of great value as the sensitiveness must be extremely great, which was tested out as follows.

Mon. May 26 '13

Worked on report of high frequency geometrical tuning with audions.

Tues May 27 '13

Tested out all other available audions inside of a solenoid but #2 was the only one which gave the discontinuity effect. Suspect the effect is due to positive ionization because

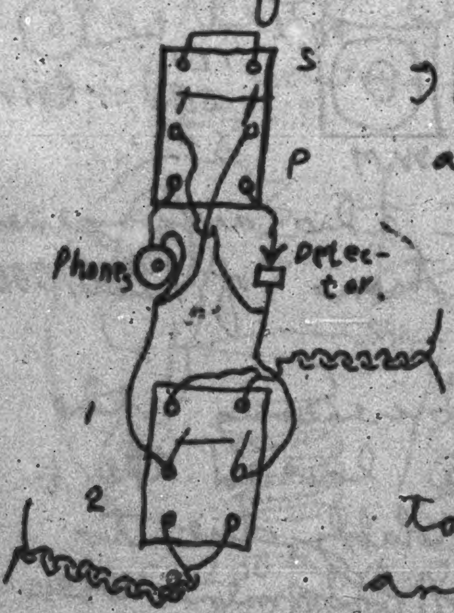
1st After operating a while there is a lag between grid E.M.F critical values depending on whether it is being raised or lowered past the point

2nd For no apparent reason the effect will sometimes mysteriously disappear and later just as mysteriously appear again.

3rd This audion #2 is the only one which shows effect and is the only one we have which has shown blue

Mr Brooks is starting a wireless receiving station in Bldg 4 and I have given him one of our audions to use. (#8) So far he has not used it to receive messages although it responds to the buzzer as well as a galena detector he is using.

Rogers has rigged up a silicon detector in connected with a couple of D.P. D.T. switches



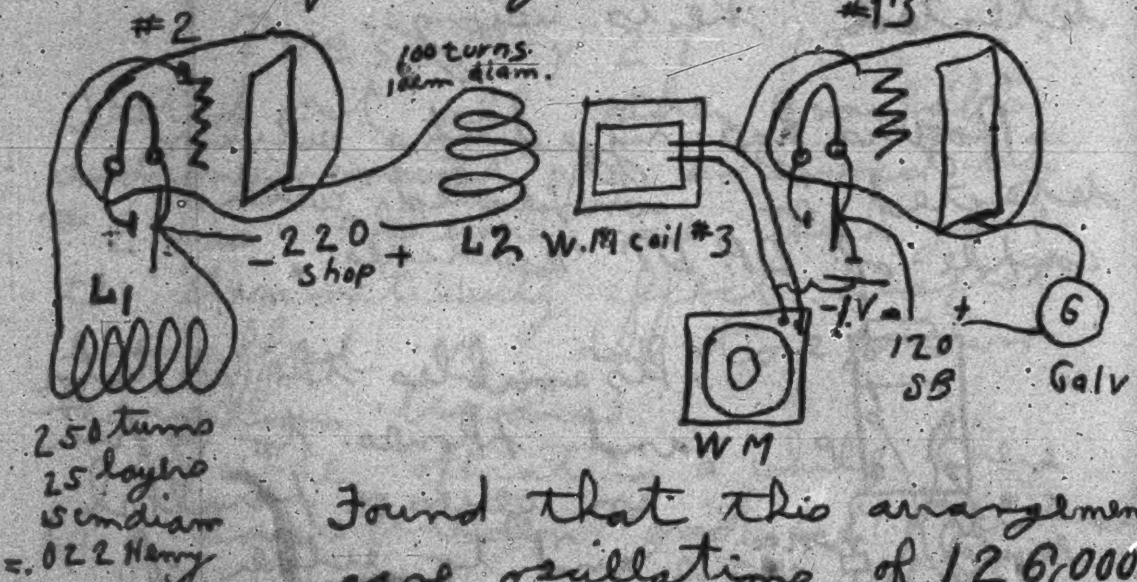
This enables the detector and phones to be put in series or parallel and to either of two circuits.

The detector seems to work fairly consistently

With this arrangement tested ~~out~~ audion # 2 as a multiplier of oscillations.

Dushman has found that when an inductance is placed in grid circuit oscillations are set up which are amplified in the plate circuit, tried to detect these oscillations on one of our small audions #2.

Used following connections



#2
100 turns. 10cm diam.
-220 shop +
L2
W.M coil #3
#13
L1
-1V+
120 SB
+
G
Galv
WM
250 turns
25 layers
15cm diam
=.022 Henry

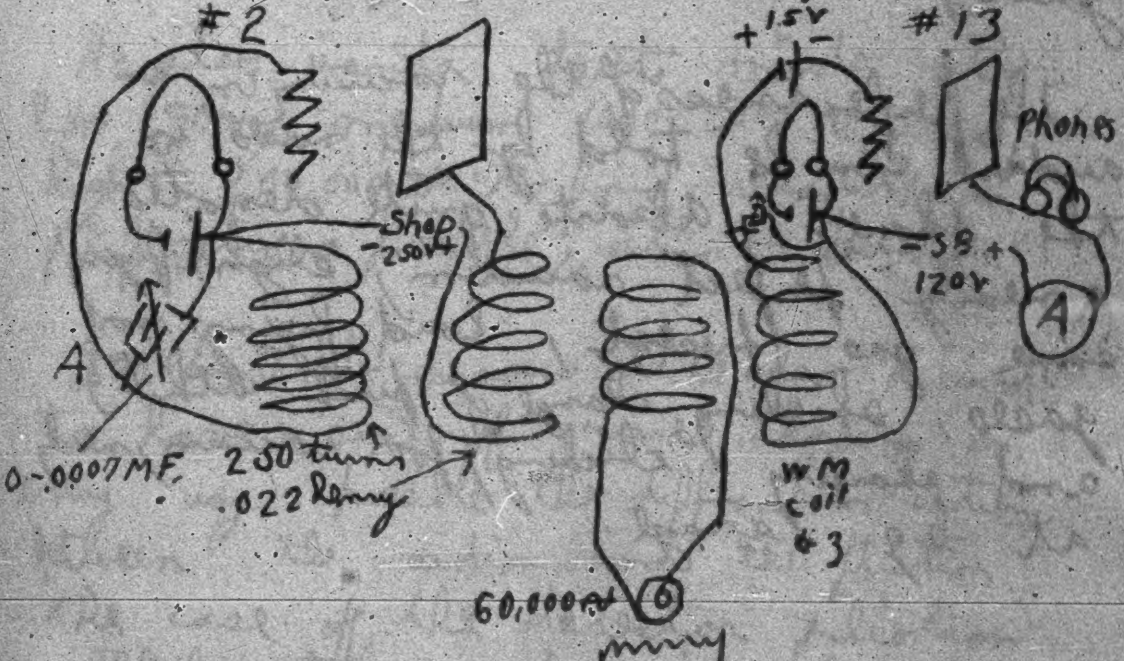
Found that this arrangement gave oscillations of 126,000 cycles per second.

Also found that increasing the filament temperature lowered the frequency. This is probably due to change in position of filament when heated causing change in capacity of audion

Increase of plate voltage

second and will neutralize the result being zero only 1000th of a second so that the effect in the phones will that of a 1000 cycle current which is easily heard. This arrangement should improve the sensitiveness of the detector for here the whole variation is made use of and not just the assymetry.

For tests the following arrangement was used on the first trial



#2

easily according to A.B.C. Allies:

Add a solution of Sodium Hypophosphite to one of copper sulphate in the cold add HCl, filter and wash precip. then wash precip in grain alcohol, result is CuH.

The same difficulty however will be experienced in freeing from contained gases,

The perfectness of the vacuum in an audion can be told by the noises in the phone. Absolute quite denotes a nearly perfect vacuum, slight frying some gas present, loud frying more gases, shrieking change of pitch with Eg and chopping clicking, poor vacuum, nearly at b-g. stage.

Dec 22 to Dec 29 1913

Had a talk with Dr Langmuir he wants some pieces of apparatus made up to demonstrate pliotrons
1st a detector outfit
2nd an amplifier "
3rd a telephone relay.

Several amplifiers should be made up so that tuning in geometrical progression may be illustrated.

He also wants tests made with low (60v) medium 1000-2000 v and high 200,000 v to find relations amplifications possible, without tuning.

For patent reasons it is also desired to have a series of curves showing in every way possible the difference in action between the audion and the pliotron the case of the detector pliotron will be taken up separately.

Report on Relaying of High Frequency Currents by Means of Improved Audions.

W. C. WHITE

May 24, 1918. N. B. 452, pp. 61-64.

The two main objects in making these tests were, first, to determine if the improved audions would relay high frequency currents satisfactorily, and second, to get a working demonstration of geometrical tuning for wireless telegraphy as proposed by Mr. Alexanderson.

A standard 2 KVA high frequency alternator was used in connection with two of the improved audions.

A Marconi Wave Meter, consisting of a resonant circuit with variable condenser, was used to show that the high frequency current was correctly and sharply relayed.

Inductive coupling by means of air core coils was used to connect the different circuits.

A diagram of apparatus and connections is attached. Thruout the tests a constant current of 2.6 amps. was kept on coil D by field regulation of the alternator, so that a magnetic field of constant value was maintained about this coil.

The grid circuit of the first audion was tuned to 66,000 cycles, the audion relaying it to the grid circuit of the second audion, which by means of the wave meter was also tuned to 66,000 cycles.

The frequency was varied between 40,000 and 100,000 cycles, and a reading of 0.126 milliamperes maintained on Meter K by varying the distance between coils C and D.

Therefore the axial distance between these coils was a measure of the responsiveness of the tuning system, the relation between this distance and the field strength relative to that at a co-planar position being known.

Then this distance, corrected as above and plotted against frequency, gave resonance curves, giving the relative responsiveness or sensitiveness to different frequencies.

Three sets of tests were made:

1. Determination of resonance curve in first audion system only, meter K being substituted for coil F to give quantitative results.

2. Determination of resonance curve in second system only, coil G being coupled directly to coil D.

3. Combination of the two systems giving geometrical tuning.

The resultant resonance curves are shown on the accompanying prints.

Comparison of the resonance in the wave meter circuit alone to its resonance when it is actuated by another tuned audion circuit shows that its responsive range is widened, while sensitiveness to frequencies outside of this range is greatly cut down.

Theory predicts that the ordinates of the curve of the two tuned circuits should be the product of the ordinates of the curves of the two circuits alone, the peak of each wave being considered as unity.

This checks up quite well on the lower portions of the curve, as the dotted line shows, but near resonance the high slope of the curves and the fact that the tuning of the component circuits was probably not closer than 2% prevents close agreement between the predicted resultant curve and the experimental.

The mere fact that sharp and consistent resonance results were obtained in the second circuit is ample proof that the improved audions are not sluggish in action. Tests made show that sharp tuning could be obtained at 105,000.

B. & S. Igniter

Platinum Contacts (Idea)

May 8, 1912.

Received tube *594836 from Wiggin. This is my first tube with a tungsten cathode. It also has a heavy tungsten anode, without any backing. It has the usual regulator, but no auxiliary anode.

Wiggin wrote that the tube was very freaky & would not do at all. My first impressions were that it was by far the "crankiest" tube I had seen. Upon passing *very* little current thro it the vacuum would go from say 3 to 8 inches, and this repeated itself over and over.

The cathode got hot easily, and I finally found that with the cathode ~~[illegible]~~ at bright redness the tube showed entirely different characteristics. The vacuum became beautifully stable and, so far as to-day's expts. show it remains so as long as the cathode is kept at bright red heat.

I have the impression tonight that this tube shows much less excess heating of the glass around the cathode & about the front hemisphere than do the regular tubes. I ran it a long while this afternoon getting intense X-rays. Behind the screen the light in the fluoroscope was very intense.

The perfect steadiness of the tube is remarkable. The glass shows a much deeper purple coloration than I have yet produced in any other tube.

The cathode shows no roughening unless it is at the very center over an area of perhaps $\frac{1}{16}$" diam. The heating at the cathode is clearly strongly localized at the center.

The tube, as it came, showed a black ring ~~around~~ on the glass around the cathode. This darkening has extended all over the bulb to a slight degree. It may be due to ~~the~~ cathode spattering of tungsten or it may be due entirely to the action of the regulator gases on W. I ~~[illegible]~~ used big quantities of the regulator gas before starting

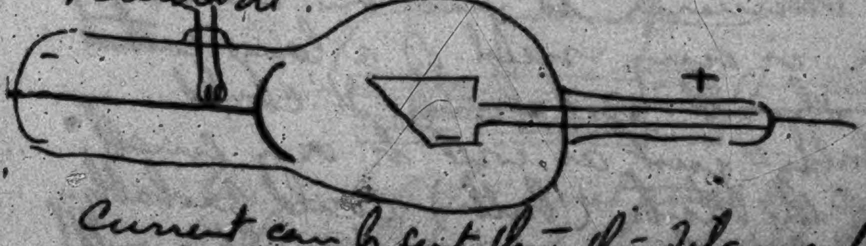
Wit. W. G. Gartner 173
Feb. 13, 1913

to run the cathode hot.

x I believe that the above points the way to the ideal X-ray tube. It looks to me now as though, with the hot tungsten cathode, the degree of vacuum would play an entirely subordinate role, provided of course it is high enough, and that there will no longer be any such thing as a too high vacuum. The tube resistance will apparently be determined by the temperature of the cathode.

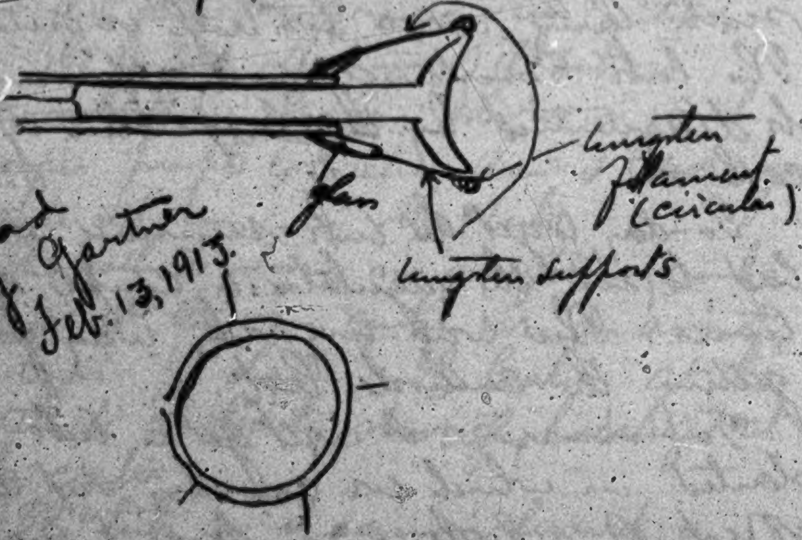
To-day, to get the tube running, I have had to use the regulator a couple of times. This was my only way for getting the cathode hot.

To-morrow I will get a tube started in which we can try out the effect of a little incandescent tungsten filament behind and close to the cathode.



Current can be sent thru the filament from a storage battery, which is insulated from the earth, and the filament can be electrically connected to the cathode.

Or a circular loop of W wire can be put around the cathode, but free from it except at one point & supported from the glass tube surrounding the cathode rod



Read
W. G. Gartner
Feb. 13, 1915.

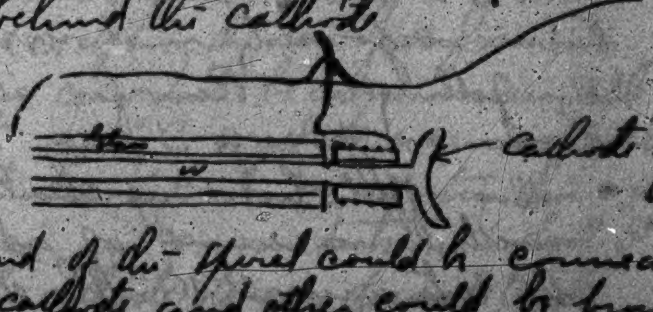
It will be very interesting with a very high vacuum to find out whether there is any need of a large cathode ~~This should not be so~~ It could probably just as well be very small. And the tube (bulb) could probably likewise be very small as it would no longer be necessary to make

it large for stability of vacuum.
A small quartz bulb only 1 or 2 inches in diameter might well be plenty large even for very high power work.

Tube 594036, described above, should, just as it is, readily permit of real moving picture work.

Heating of the cathode might well be made very easy by attaching a hollow stem to it and putting a rod of Chester Moore's sheath wire inside the hollow stem

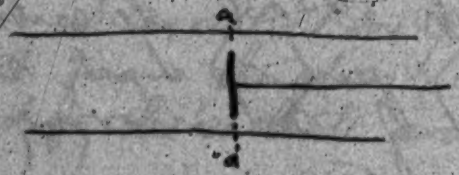
Another very simple stunt might be to wind a tungsten spiral on a thin silica ~~tube~~ or alumina spiral and to slip this ~~tubing~~ on over the cathode supporting rod just behind the cathode



One end of the spiral could be connected to the cathode and other could be brought out through the side of the tube wall

This was repeated over & over

The tube is badly blackened near the target the blackening being



worst at a-a, with none behind here (the line is very sharp) and gradually decreasing towards the cathode.

Sept. 24, 1912

Working with X-ray tube made up by Joe Clayson. W cath. & heavy W anode 7" bulb.

Tube is not in heater. Used Bunsen burner vigorously on it several times H_2 filling. Ran for about an hour on pump.

One effect shows up clearly. Starting with a vacuum of say 20 micron the tube runs O.K. The electrodes both heat up strongly, and there is a as our Cadillac units were ready I would go with him to the Cadillac Co., & to see Kettering, to get them tested out.

Dr. Hubbard from Clark Univ. was here & talked at Colloquium on the spot measurement of the period of oscillation in high frequency circuits.

Dec. 8, 1912.

If disapp. of gas in a tube is due to chem. action, there should be more of it in case of a bulb of fused quartz. Test this out some more.

Dec. 10, 1912.

Dr. Langmuir tells me that, in his study of Edison Effect, the current, in the case of a hot cathode, is greater with a very fine vacuum of 1 or 2 hundredths of a micron than it is at higher gas pressures (excepting the case of Argon). His Edison currents become measurable at about 1600° C & get to a max. value at about 2300° C. I will try this out at once in an X-ray tube in which I can heat the cathode to any desired temp. The above would be in line with my observations on pgs. 171 – 175.

PLAINTIFF'S EXHIBIT No. 175.

Extracts From Coolidge Note Book No. 446.

Feb. 17, 1913.

Worked with Tube 112 this P.M. It has a very small hole in the cathode plate (1" radius of curvature) with the filament point just sticking in to the hole, and the target is placed much closer to the cathode.

From the very first turning on of the current this tube has focussed sharply. As a result, it has been easy to heat the target so as to get the gas out of it. The tube was therefore in excellent condition after perhaps 1 hour's work ~~with~~ on it after it had come out of the oven. The electrodes were fresh ones, so this expt. demonstrated conclusively that the target has been the troublesome source of gas, and the lack of focussing when running as an ordinary tube, that is before getting a good vacuum has been what has made the tube exhaust so tedious and precarious.

The new 1000~ circuit will be completed by to-morrow morning, but our need for it is certainly lessened by to-day's expt. It will clearly be much better to so design the tubes for permanent work that they shall focus in case the

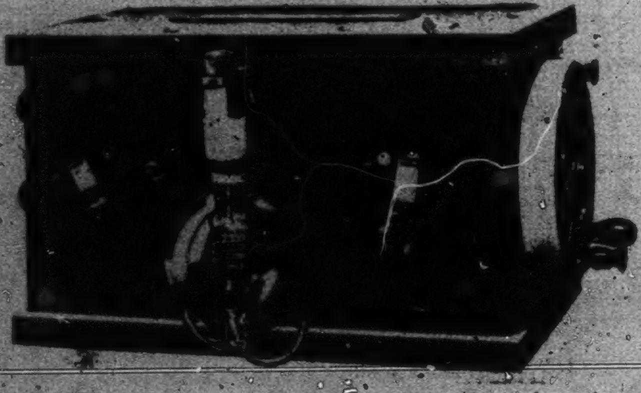
Bulletin B 14

DeForest
Audion Detector

Licensed for private, amateur or experimental use only. The only Audion Detector manufactured for the use of amateurs under the protection of the patents of Dr. Lee deForest.



THE deFOREST AUDION DETECTOR
IMPROVED TYPE RJ4.

Licensed for Private Use Only

THIS instrument represents the highest development of wireless detecting apparatus known to science.

Tests conducted by the United States Bureau of Standards have shown it to be fully 50 per cent. more sensitive than any other form of detector (Bulletin, Bureau of Standards, Vol. 6, No. 4, P. 540).

Its adjustment is instantaneous, and is unaffected by mechanical or electrical disturbances.

This instrument is complete in itself, the only necessary connections being to the secondary terminals of the tuner, to the phones, and to a four volt battery. All these connections are plainly marked on the cabinet.

Throwing on the switch at the right of the Audion bulb to the left or right lights one or the other of the filaments. The battery switch at the left of the lamp and the rheostat lever are then moved to a position where signals are at their best. After these adjustments are once made, the throwing off of the switch instantly places the detector out of service. *Do not keep the Audion bulb lighted when not using the instrument.*

These detectors are thoroughly tested before shipment, and are guaranteed to leave our factory in perfect working order.

Price for the instrument complete as illustrated, $18.00

This detector may be operated by three dry cells. The best results, however, are obtained from the use of a storage battery.

4 volt 30 ampere hour storage battery, $5.00

THE deFOREST AUDION DETECTOR
TYPE RJ5.

Licensed for Private Use Only.

This instrument is complete in itself, the only necessary connections being to the secondary terminals of the tuner, to the phones, and to a four volt battery. All these connections are plainly marked on the cabinet.

Throwing on the two point switch at the right of the Audion bulb lights one of the filaments. The battery switch at the left of the lamp and the rheostat lever are then moved to a position where signals are at their best. After these adjustments are once made, the throwing on or off of the two point switch instantly places the detector in or out of service. After the first filament has been consumed wind the little copper wire tight around the brass base of bulb underneath the rubber band. This connects the second filament.

These detectors are thoroughly tested before shipment, and are guaranteed to leave our factory in perfect working order.

Price for the instrument complete as illustrated, $25.00

AUDION BULBS FOR RENEWALS.

The sensitiveness of Audion bulbs has been still further improved of late. We make two grades, the "S" or standard, and the "X" or extra sensitive. *Audion bulbs are sold only as renewals, or to those who have purchased our Audion Receiving sets,* and then only on the return of the old bulbs.

Renewal bulbs, "S" grade, $3.50 each.
Renewal bulbs, "X" grade, $5.00 each.

INSTRUCTIONS.

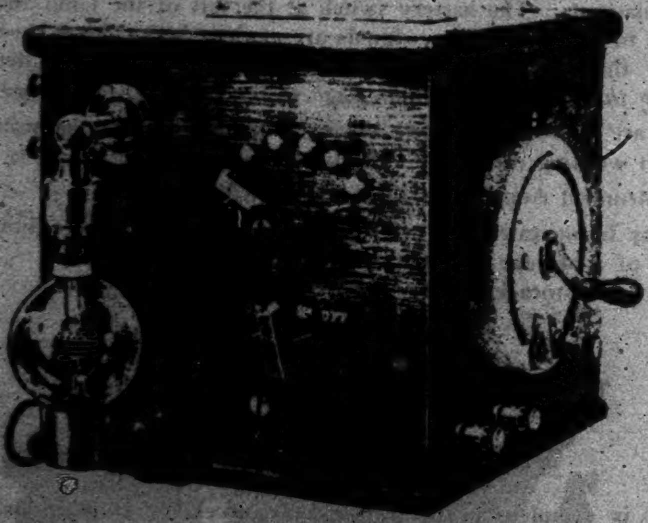
To get the very best results follow instructions explicitly.

Do not connect over six volts storage battery to the external binding posts marked + and —. Before lighting the filament see that the resistance switch is on the "1X" position. Then adjust rheostat until lamp burns at normal brightness. Adjust brightness of filament and the battery B switch to give maximum sensitiveness.

In connecting up the Audion Detector, connect the grid to G and wing to W, as marked below the binding posts. The Grid is the zig-zag wire terminal. The Wing is the plate.

If bulb is capped the green wire leads to the grid, the red leads to the wing.

Connect the little copper wire at base of bulb to the binding post directly beneath the bracket. This connects in the second filament to one point of the battery A, or lighting switch. The other filament is connected through the lamp socket to the other contact point. If one filament is more sensitive than the other reserve this for long distance work.



TYPE RJ6

The Audion has been proven, by scientific and official tests to be from 1.5 to 3 times as sensitive as any crystal detector. With it even in this small and cheap form, telegraphic ranges far greater than those possible with the crystal or electrolytic detectors are easily attained.

It is reliable, requires no adjustment after the proper voltage and heating currents are determined, it cannot be injured by powerful transmitter sparks in the immediate vicinity. If it momentarily loses its sensitiveness by reason of the transmitter spark, it is automatically restored, without the slightest decrease in its sensitiveness.

Receiving ranges with the Audion detector are far greater than with other types.

We have many testimonials from users of the Audion describing surprisingly long distances over which messages are being received, and the extraordinary strength of long distance signals.

If too much "Battery B" voltage be applied a blue glow will appear in the bulb, or may be seen merely around the edges of the "plate" or wing. When this blue glow fills the bulb it is usually not very sensitive. The glow can be removed by simply reducing the B voltage by the 3-point switch on the RJ4 and the 6-point switch on the RJ5. The sensitiveness can be instantly restored by merely switching off and on the lighting current. Only one filament should be burned at one time. This doubles the life of the bulb.

Never burn the filament at excessive brilliancy, as full sensitiveness can be obtained at normal brilliancy.

Always use a storage battery for lighting the lamp, as dry cells run down very quickly when used for that purpose.

Never use more than three cells of storage battery.

Don't let the storage cells run down low and then hook in another fourth cell, because if this is done there is always danger of the run-down cells picking up, or recuperating after a short period of rest and then of burning out the filament when first switched on again.

Connect the secondary of the receiver tuning circuit to the binding post marked "Tuner."

It makes some difference in the results obtained which of these two terminals is connected to one or the other of the two "Tuner" binding posts. The surest way of determining this is to reverse the two connections, and thus observe which gives the louder signals.

(The RJ4 and the RJ5 Audion are for *Amateur* work only and are *not* under any conditions licensed to be used for commercial work.)

We also manufacture other deForest Audion types as follows:—

Audion Detector, P.N. type, licensed for commercial work, each	$ 50.00
Audion Amplifier, one step, each	150.00
Audion Amplifier, two step, each	300.00
Audion Amplifier, three step, each	500.00

Improved Type RJ4 Audion Detector.

Manufactured by

DeForest Radio Telephone & Telegraph Co.

101 Park Avenue, New York.

Cable Address: Radiotel, N. Y.

REGARDING THE DEFOREST AUDION DETECTOR.

THIS instrument represents the highest development of wireless detecting apparatus. It is the most sensitive and reliable detector in existence. Tests conducted by the United States Bureau of Standards have shown it to be fully 50 per cent more sensitive than any other form of detector (Bulletin, Bureau of Standards, Vol. 6, No. 4 P.540).

One of its greatest advantages over other detectors is its reliability. When once the proper voltage and heating currents are determined, no further adjustment is required. If powerful electrical impulses in the immediate vicinity should momentarily decrease its sensitiveness by their very strength, the Audion will generally restore itself at once automatically, but otherwise, turning the high voltage switch back one point and bringing it to its original position, will bring back full sensitiveness positively and at once.

The Audion Detector is not affected by any ordinary mechanical vibration and is not appreciably affected by the spark of the transmitting apparatus. It will stay in adjustment indefinitely and can be depended upon at all times. Its use enables the operator to receive over the greatest distances possible with any form of detector.

Each DeForest Audion Detector is supplied complete at the prices listed, with the necessary switches, rheostat, fixed condenser and the battery "B", *but without* the battery "A", which is composed of a six volt storage battery or three or four dry cells, preferably the former. *Never use more than six volts* for this battery, which is connected to binding posts on the outside of the case marked AA. All Audion bulbs have 3½ volt filaments.

The battery "B" is located inside the case and is composed of a number (from 10 to 12) of three cell flashlight dry batteries.

The proper methods of using the various styles of DeForest Audion Detectors, are described in this bulletin, and these instructions given for operating the detectors should be followed carefully if the highest efficiency is desired for the station.

All our Audion Detectors are regularly furnished with Standard "S" grade Audion bulbs. The "X" grade will be supplied at the additional prices as given in the PRICE LIST in this bulletin.

THE DEFOREST AUDION DETECTOR

IMPROVED TYPE RJ4.

Licensed for Private Use Only.

This type of Audion Detector is now employed very generally in amateur stations. Like all our Audion Detectors, it is complete in itself with the exception of the Battery "A" which consists of a six or four volt storage battery, or three or four dry cells, preferably the six volt storage battery. Batteries may be purchased from any electrical supply house.

The Type RJ4 Detector is made in a mahogany case and now has a five point Battery "B" control switch instead of three points as shown in the illustration. This gives very close regulation and has greatly improved the efficiency of the detector.

This detector is recommended to those who desire to increase the receiving range of their stations, and who wish the greatest possible reliability of operation. Customers who have purchased Audion Detectors write us that they have discarded all other forms of detectors and use the Audion exclusively.

DIRECTIONS FOR TYPE RJ4 AUDION DETECTOR.

The proper method of connecting the Type RJ4 Audion Detector is described below. It may be used with any wireless receiving set, but best results are obtained with it in connection with a good receiving transformer, and a variable condenser. Simply connect the secondary terminals of the receiving transformer to binding posts on the Audion Detector marked "Tuner". Connect the telephone receivers to the binding posts marked "Telephone". The receivers for all types of Audion Detector should have a resistance of 1000 ohms or more each.

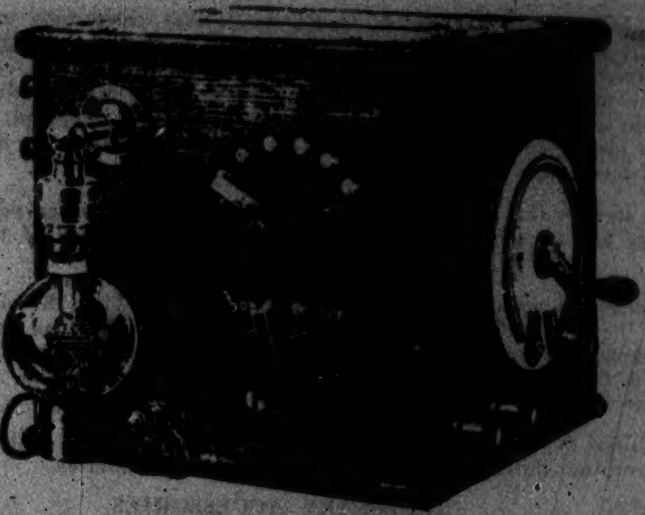
Turn the lever of the porcelain base rheostat (on the right hand end of the case) around to the left as far as it will go, so that it points downward and toward the front of the case. Screw the Audion bulb in the socket and connect the red wire (or wire leading out from the wing or plate of the bulb) to binding post marked R. Connect the green wire (or wire leading out from the grid or zig zag of the bulb) to binding post marked G.

The two point switch at the right of the bulb lights or extinguishes the filament. Light the filament and adjust the five point switch at the left, which controls high voltage battery "B" located inside the case until a slight hissing sound is heard in the receivers, when the filament is bright up to normal incandescence by means of the rheostat. Be careful not to burn the filament too brightly as this would shorten its life and will not materially increase its sensitiveness.

Each detector bulb has two filaments, one of which is connected in circuit when the bulb is screwed in the socket. When this filament burns out, the second is connected by simply twisting the wire projecting from the base, around the screw base and securing it under the rubber band.

Do not fasten any of our instruments by using screws long enough to penetrate the case. This might short circuit the internal condenser or batteries.

THE DEFOREST AUDION DETECTOR
TYPE RJ5.
Licensed for Private Use only.



Type RJ5 Audion Detector.

The Type RJ5 Audion Detector is a larger instrument than the Type RJ4 and is of higher grade construction throughout. The case is of oak with a dark waxed finish and all metal parts are heavily nickel plated. The switches are of four ply laminated construction, insuring positive contact, and the switch knobs are of genuine hard rubber. The battery "B" control switch has six points, permitting very close adjustment.

Instructions for operating and connecting this instrument are the same as for the type RJ4 Detector.

All our detectors are tested thoroughly before shipment and are guaranteed to leave our factory in perfect working order.

If too much battery "B" voltage is applied in any Audion Detector, a blue glow will appear in the bulb, or may be seen around the edges of the plate or wing, and a roaring sound will generally be heard in the telephone receivers. When this blue glow fills the bulb it is usually not very sensitive, and if this discharge is allowed to persist for a time, the bulb will become "hard", and will require a higher battery "B" voltage.

The discharge can be stopped by simply reducing the battery "B" voltage by the 5 point switch on the Type RJ4 or the 6 point switch on the Type RJ5 Detector. The sensitiveness can be restored instantly by switching off and on the lighting current.

A "hard" bulb can be "softened" by heating very carefully and evenly over a flame for a few minutes.

Audion Bulbs are sold for renewal purposes *for our instruments only* and then *only on return of an old bulb or the wing and grid system of an old bulb.*

Connect "Battery A", a 6 volt storage battery, or four dry cells, to binding posts AA, and try reversing these connections as this will make a difference. If dry cells are used, be careful to bring the rheostat lever back after using the detector, because the dry cells will recuperate on standing and their voltage will increase, which might burn out the bulb when turned on again.

Never use a higher voltage than 6 for this purpose.

Don't let the storage cells run down low and then hook in another fourth cell, because if this is done there is always danger of the run-down cells picking up, or recuperating after a short period of rest and then of burning out the filament when first switched on again.

It makes some difference in the results obtained which of these two terminals is connected to one or the other of the two "Tuner" binding posts. The surest way of determining this is to reverse the two connections, and thus observe which gives the louder signals.

THE PURPOSE OF THE DEFOREST AUDION TIME RECEIVER.

Time signals are sent out by radio (wireless) telegraphy every day by the U. S. Government station at Arlington, a suburb of Washington, D. C., at 12 o'clock noon and 10 P. M., Eastern Time. These signals are simply a succession of dots, starting five minutes before the hours mentioned above and terminating in a dash, which begins exactly on the hour. No knowledge of the telegraph code is therefore required to obtain correct time, and this is a great advantage to anyone not skilled in wireless telegraphy.

These signals travel at the rate of more than 16,000 miles per second, so that an accuracy can be obtained which is greater even than that of the ordinary telegraph.

No license is required for operating our Audion Time Receiver and there is charge by the Government for the time service. Practically no knowledge of electrical apparatus is required to obtain excellent results with the Audion Time Receiver, and full directions are given in this bulletin to enable anyone to install and operate it.

The initial expense is practically the only expense, as the set should cost not more than three or four dollars a year to maintain, for new batteries.

NECESSARY ACCESSORIES.

The only accessories needed to form a complete time receiving station, in addition to our Audion Time Receiver, are a first class double head set wound to 2000 ohms or more, a quantity of aerial wire, a few aerial insulators, four dry cells or a six volt storage battery and a switch for connecting the aerial to ground when not in use, which is all that is required by the Fire Underwriters.

THE AERIAL AND GROUND.

Several types of aerial or antenna may be employed for receiving the time signals depending on local conditions. The higher the aerial wires are placed, and the longer, up to a limit of a 300 foot stretch, the better for the purpose and the louder the signals will be. Satisfactory results cannot be obtained generally with stretches of less than 100 feet.

Wherever possible, the flat top or the inverted L type should be used but the other forms may be employed if the former cannot be conveniently installed. Several good types are shown in the drawings. The aerial wires should be of stranded copper or some strong bronze, but iron or aluminum should not be employed for the purpose.

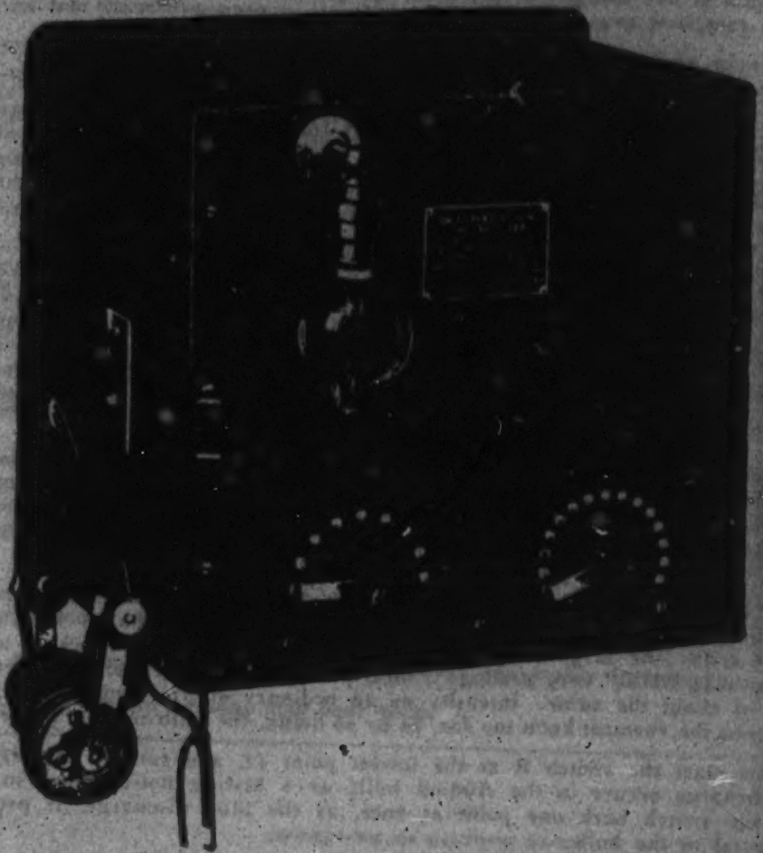
All aerial wires *must* be prevented from touching any objects except insulators, and the diagrams show the proper manner of supporting the aerial system.

A ground connection is best made by connecting to a city gas or water main by means of a ground clamp. When gas or water pipes are not available, a ground connection may be obtained by driving a one inch (not painted) iron pipe at least four feet into the earth in a moist place, and connecting to the pipe by means of a ground clamp. The wire leading to the ground connection need not be insulated.

The *Lighting Switch* has a special waterproof base. It is placed outside the building at the point where the continuation of the aerial wires enter, and is connected separately to the ground in a straight line, by means of No. 4 weatherproof wire. This is a different ground connection than the one for receiving purposes, and is made to an iron pipe driven into the earth at least four feet. The diagram shows the arrangement of the switch and its connections. It will be noted that when the blade is in one position, the apparatus is disconnected from the aerial which is connected to the earth, and in the other position the apparatus is connected to the aerial.

The switch should be left in the former position at all times when the apparatus is not in actual use, simply as a precaution.

THE DEFOREST AUDION TIME RECEIVER



The deForest Audion Time Receiver has been placed on the market to meet a strong demand for the highest grade, most serviceable set for receiving the Government time signals. It is designed primarily for this particular purpose, and will therefore, show a much higher efficiency for this work than any outfit made for general purposes of receiving messages.

This receiver uses as a detector, the famous deForest Audion Detector, which is the *most sensitive* and *reliable* device of its kind in existence (bulletin U. S. Bureau of Standards, Vol. 6, No. 4, p. 540). The deForest Audion Detector is the only highly sensitive detector which when once adjusted, will remain in perfect adjustment indefinitely, irrespective of mechanical vibration or the presence of powerful transmitting apparatus in the immediate vicinity. With its use the owner is assured of *reliable* service every day in the year, and at the greatest possible distance from the origin of the signals.

In addition to employing this peerless detector, we have combined, in a single case of waxed piano finish oak, the necessary tuning apparatus, so arranged that anyone can receive time signals positively and accurately without electrical knowledge or experience.

When once the set is adjusted, it will remain so from one end of the year to the other. When through using the set, simply hang the head receivers on the hook at the left so that it falls, which automatically shuts off all circuits, and when at any subsequent time it is desired to receive the time signals, lift the receivers off the hook at five minutes before noon or 10 P. M., Eastern Time, and place them over the ears, and you will hear the signals *every time positively* and *without fail.*

It is in reality a professional instrument, licensed only for private use. It measures 13 inches long, 11 inches wide and 11 inches high.

The case is of oak with a high waxed piano finish, all metal parts are heavily nickel plated, and all switch and control knobs and binding posts are of genuine hard rubber. The front panel is of black composition in great contrast to the nickel trimmings. The instrument is of such a high grade appearance as to harmonize with the very best of surroundings. From the standpoint of operating efficiency, it leaves nothing to be desired and the illustration shows its extreme simplicity.

DIRECTIONS FOR THE DEFOREST AUDION TIME RECEIVER.

Connect the wires running to the aerial through the lighting switch to the binding post on the set marked A. Connect the ground wire to binding post E. Turn the hard rubber knob under the lamp socket so that the pointer indicates "IN." Connect a six volt storage battery or four dry cells, preferably the former, to the binding posts marked AA. Connect the tips of the head set to the binding posts marked TEL.

Screw the Audion bulb into the lamp socket, and connect the wire leading out from the grid in the bulb to binding post G, and the wire leading out from the wing in the bulb to binding post R. (The grid is the zigzag of wire, and the wing is the metal rectangle.) If the wires leading from these parts are colored red and green connect the green wire to G and the red wire to R.

At five minutes before the hours on which the time signals are sent, Eastern Time, lift the head set off the hook and the bulb will immediately light. Turn the rheostat knob (the larger of the two directly under the lamp socket) away from "IN" toward "OUT," very gradually, until the filament of the bulb becomes normally bright, of about the same intensity as an ordinary electric lamp. Use great care not to turn the rheostat knob too far, as by so doing, the bulb will be burned out.

Now start the switch B at the lowest point 12, and turn to the right until a blue discharge occurs in the Audion bulb, or a hissing noise occurs in receivers. Bring the switch back one point at once, as the blue discharge, if prolonged, is detrimental to the bulb.

Move the switch knob PC from the lowest, left hand contact point, around the arc, in the meantime moving the knob LC slowly, until the high pitched time signals come in loudest. When this occurs, the set is in "tune" with the Arlington station.

If other signals should interfere with the time signals, simply turn the knob LC or VC to the left to reduce the interfering signals, and adjust slightly the switch knob PC for the best results.

No further adjustment will be needed. When finished, simply hang the head set on the hook, so that the light in the Audion bulb is extinguished, and the next time the correct time is desired, simply remove the head set from the hook and the signals will be heard without any adjustments whatever.

Do not leave the bulb lighted when it is not in use for this would reduce the life of the bulb.

If dry cells are used to illuminate the filament it should be remembered that in this service, their voltage drops off rapidly, and after standing, they will recuperate. Therefore, after using the set, the rheostat knob should be turned toward "IN" so that when the set is used again, the increase of voltage of these batteries will not burn out the bulb.

For other directions see those for types RJ4 and RJ5 Audion Detectors.

COST OF THE OPERATION.

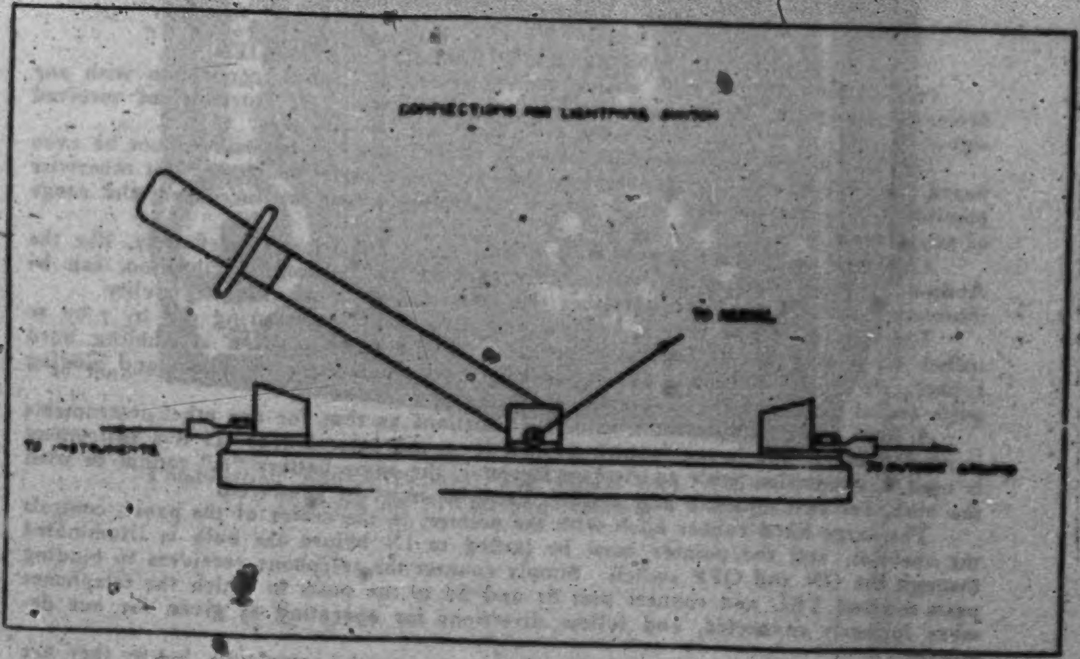
After a period of from eight months to a year, the small flash light batteries contained inside the case will become exhausted, whether the set is used or not. A new set of the common batteries can be obtained from any electrical house, and these may be readily connected in circuit. They must be connected in identically the same way as those now in the case.

The Audion bulb should last for a year or longer, if it is used for time signal reception only, and is not burned at excessive brilliancy. It will be noticed that each Audion bulb has two filaments. When the original filament burns out, the second is connected in circuit by merely twisting the fine copper wire around the brass base of the bulb under the rubber washer so as to make contact with the base.

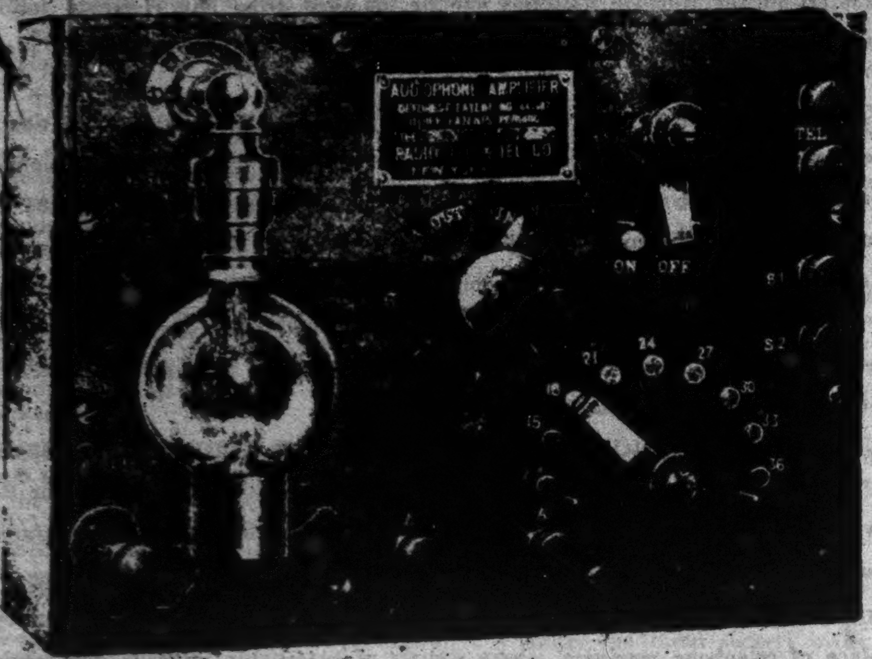
The batteries used determine their cost, but four good dry cells should give at least 30 useful actual operating hours, and a 30 ampere hour storage battery should provide 60 operating hours on a single charge.

USE OF THE AUDION AMPLIFIER WITH THE AUDION TIME RECEIVER.

The use of our Audion Amplifiers in connection with the Audion Time Receiver will permit reception of time signals where no other outfit can give satisfactory results. Wherever received signals are very weak, the amplifier will bring them in strongly, and if desired a loud speaking, high resistance horn may be employed in place of telephone receivers, where signals of reasonable intensity are received, so that any number of persons may hear them.



THE SINGLE STEP AUDION AMPLIFIER
Licensed for Private or Amateur Use Only



TYPE PJ1 SINGLE STEP AUDION AMPLIFIER.

The Audion Amplifier is an instrument which is used in connection with any detector, preferably an Audion Detector, for increasing the intensity of received signals from 5 to 10 times. It is not a detector itself in any way.

Through its use, messages can be read clearly which otherwise cannot be even heard. Its use enables the operator to receive over ranges which are not otherwise possible. it is the greatest improvement of modern times for increasing the range of any station.

This type of Audion Amplifier will remain in adjustment indefinitely, like the Audion Detector, and is not appreciably affected by mechanical vibration, can be thoroughly relied upon, and amplifies the weak signals with absolute fidelity.

The case is of oak with a high waxed piano finish, measuring 9¼ by 7 by 10 inches deep over all. The front panel is of black composition resembling hard rubber. All metal parts are heavily nickel plated and the switch knobs and binding posts are of genuine hard rubber.

A local battery "A" of the same specifications as that for our other instruments is needed for it but is not furnished with it at the price listed. If this instrument is used in connection with an Audion Detector, the same battery "A" cannot be used for both, but two separate and distinct batteries must be employed.

The large hard rubber knob with the pointer, in the center of the panel, controls the rheostat, and the pointer must be turned to IN before the bulb is illuminated through the ON and OFF switch. Simply connect the telephone receivers to binding posts marked TEL and connect post S1 and S2 to the posts to which the telephones were formerly connected, and follow directions for operating as given for our detectors.

Both filaments of the Amplifier Bulb are used at the same time, but as they are burned at a lower temperature than those of an Audion Detector, they have a very long life.

DE FOREST COMBINATION
AUDION & AMPLIFIER
DE FOREST RADIO TEL & TEL CO.
NEW YORK

Combination Audion Detector and Single Step Audion Amplifier
Licensed for Private and Amateur Use Only.

COMBINATION AUDION DETECTOR AND SINGLE STEP AUDION AMPLIFIER.

Licensed for Private Use Only.

In this instrument are combined an audion detector and single step amplifier, giving the operator in one instrument all the advantages of the ordinary deForest Audion Detector (in itself from 1.5 to 3 times the sensitiveness of the crystal or electrolytic detectors) plus a five-fold amplification of these signals.

Equipped with this combination set an operator has an immense advantage over all those who use other types of detectors. We find this instrument is particularly attractive to all the higher class of operators, as in addition to enabling them to easily read stations many hundreds of miles further than can their neighbors, it tremendously simplifies the labor, and heightens the pleasure of wireless receiving. This on account of its utter dependability, and freedom from all delicate and frequent adjustments. When once the battery switch and rheostat are correctly set the operator *knows* that if he is once tuned to the distant station he will hear it *every time* it calls.

Moreover, on account of the extreme efficiency of the Audion detector and the negligible damping which it adds to the secondary receiving circuit, tuning with the Audion is much sharper than with other forms of detectors. Much looser coupling may be used, with corresponding freedom from interferences. Especially does this last feature hold for the combination detector and amplifier instrument, wherewith it is easily possible to couple so loosely that all signals, and static as well, are first rendered entirely inaudible with any unamplified detector, and then to bring up the signals (especially if slowly damped wave-trains be used) to a full audible intensity. By this means it is possible to read long-distance messages through static disturbances which render other forms of receivers inoperative.

In this connection we recommend increasing the damping qualities of the antenna system, by inserting therein a variable non-inductive resistance (as practised by Dr. Austin of the U. S. Bureau of Standards) to render same as nearly a periodic to static impulses as possible. It is then found that the Amplifier can still bring up the strength of signals over that of the static more than enough to compensate for their reduction by this added resistance.

Combinations of the Audion Detector with the two-step Amplifier and also with the three-step Amplifier are made.

The case of this instrument is of oak, with a high waxed piano finish. It measures approximately 9½ by 18 by 15 inches over all. All metal parts are heavily nickel plated and all switch knobs and binding posts are of genuine hard rubber.

The lower bulb is that of the detector, and the upper one is the amplifier bulb, which has two grids and two plates.

The secondary terminals of the receiving transformer of the regular receiving set are connected to binding posts RA and RE. Reversal of these connections sometimes increases the efficiency of the set. A large variable condenser also connected to these posts is of great value in tuning.

The detector may be used alone by connecting the telephone to I TEL. If both detector and amplifier are to be used, connect this pair of binding posts to posts S1 and S2, and connect the telephone to posts II TEL. Each bulb has its individual control switches. B1 and B2 control each battery "B," and each bulb has its own rheostat lettered OUT and IN.

All other directions for operating are the same as given herein for the Types RJ4 and RJ5 Audion Detectors.

Try reversing connections of both "A" batteries for best efficiency. Two separate "A" batteries are required for this instrument.

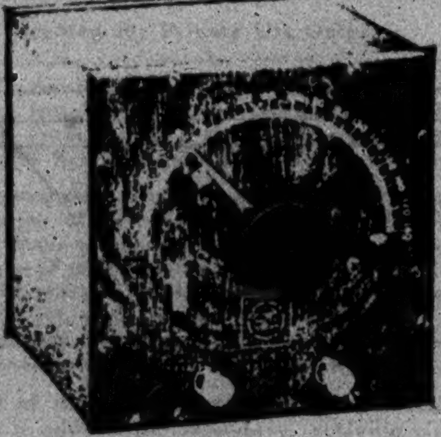
INCLINED AERIAL

DEFOREST VARIOMETERS

TYPE RJ



DeForest Variometers represent one of the most modern and efficient means of tuning sharply to incoming signals. They have no "dead ends," as all the wire is used all the time. There are no switch points or sliding contacts to cause waste of the minute received currents through their resistance.

These Variometers are extremely sharp in tuning. They give excellent results through interference, and are recommended to every operator. They may be placed in a vertical position or horizontally as they are balanced so that they remain in any position where set. All adjustments are made with a single hard rubber knob, which simplifies tuning to a remarkable degree. The Variometers are provided with a short circuiting attachment on the pointer so that they may be cut out of circuit at will. They give excellent results when used as loading coils.

The type RJ Variometer has a range of inductance corresponding to wave lengths from approximately 200 meters minimum to 1500 meters maximum, and of course this is increased by the inductance of the aerial of the station.

These Variometers measure approximately 7¼ inches square by 9 inches high over all. They are made up in polished oak cases, with genuine hard rubber knobs and nickel plated metal parts.

For long waves, two or more Variometers may be used in series.

RENEWAL AUDION BULBS

Audion Bulbs are sold *for renewal purposes, for our instruments only, and then only on return of an old bulb or the wing and grid system of an old bulb.* They are not licensed to be used in any but deForest apparatus, and under positively no circumstances will we be responsible for their action in other than our apparatus. Amplifier Bulbs are not renewable in place of detector bulbs.

The quality and life of Audion Bulbs have been much improved recently, so that the average operating life is about 800 hours if properly used. While we cannot guarantee the life of a bulb, actual tests of bulbs selected at random showed even as greater life than this. So much depends upon the proper use of bulbs, however, that no guarantee of life can be given.

Audion Bulbs are furnished in two styles—those of standard degree of sensitiveness (style "S") and those of especial sensitiveness (style "X"). Every bulb is given two tests before leaving our factory, against a standard.

Amplifier bulbs are supplied only in "X" grade, in tantalum filament and Hudson or tungsten filament types. The latter types have from two to three times the operating life of tantalum filament bulbs.

Each bulb is packed with extreme care, and we cannot be responsible for breakage in transit. In general, very few bulbs are damaged in this way, and when this does occur, the plate simply becomes jarred out of line. It can be brought back easily by simply tapping the bulb against the hand in the proper direction, taking care that the plate and grid do not strike the filament.

RENEWAL BATTERIES FOR "BATTERY B" IN ALL DETECTORS AND AMPLIFIERS.

In each Audion Detector and Amplifier a number of flashlight batteries are contained. Each battery contains three cells and tests four to five volts. The current taken from these batteries is exceedingly small and they therefore generally last from eight months to two years from the time they leave our factory.

The first sign of their exhaustion occurs when received signals gradually weaken or decrease in intensity, providing that the "Battery A" or external battery is in good condition.

When this occurs, simply remove the cover of the detector and test each battery with a voltmeter, *not an ammeter,* and replace every battery testing four volts or less, being sure to connect in exactly the same way as the cells removed, that is, carbon to zinc, so that the batteries are all in series.

New batteries of the same size and voltage, which *must* be used, can be obtained from any electrical dealer, or we will furnish them at 25 cents each F.O.B. New York City.

PRICE LIST F.O.B. NEW YORK, N. Y.

Type RJ4 Improved Audion Detector	$ 18.00
Type RJ9 Audion Detector	25.00
Type PJ Single Step Audion Amplifier	65.00
Combination Audion and single step Audion Amplifier	110.00
DeForest Audion Time Receiver, less Telephones and Accessories	75.00
Special High Resistance Loud Speaker Telephone with Horn	50.00
Type RJ DeForest Variometer	20.00

Renewal Audion Bulbs*

Type S, Standard Grade Audion Bulb	3.50
Type X, Extra Sensitive Audion Bulb	5.00
Renewal Amplifier Bulb (Tantalum Filament)	6.00
Renewal Amplifier Bulb (Hudson Filament)	7.50

Above prices subject to change without notice.

We are in a position to furnish all accessories needed for the deForest Time Receiver, and will submit prices on request.

*AUDION BULBS WILL NOT BE SOLD OR LICENSED TO BE USED EXCEPT WITH OUR APPARATUS. Renewal bulbs supplied only on return of the wing and grid system of our burned-out bulbs.

All forms of Audion, Amplifier and Ultraudion protected by the following U. S Patents granted to Lee de Forest.

824,637	836,070	837,901	841,387	867,877	879,532	943,969

Other Patents Pending.

Most wireless dealers handle our Audion Detectors and Amplifiers. Write us for name of nearest dealer.

If your dealer does not carry a stock of our instruments, he will order them for you, or otherwise we shall be glad to receive your order direct.

The price of Hudson and Tungsten filament Audion detector bulbs has been reduced to the old prices of tantalum filament detector bulbs.

PLAINTIFF'S EXHIBIT No. 179.
DeForest Bulletin C-16 of 1916.

Bulletin C 16

De Forest
Type T Tubular Audion Bulb

"There is only one Audion - The De Forest"

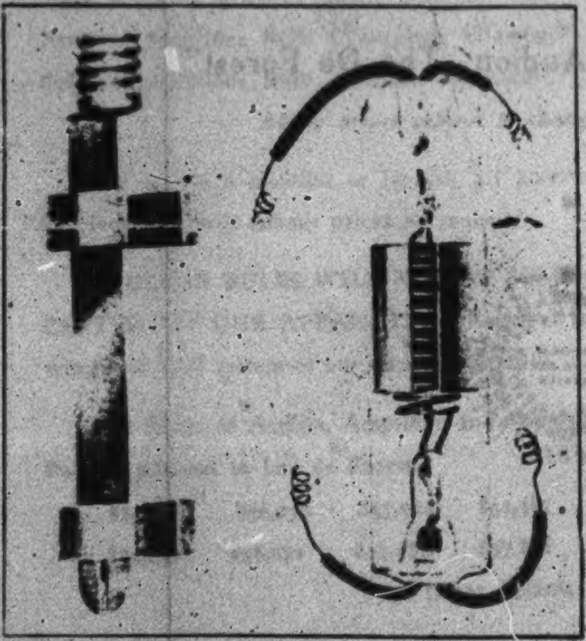
Manufactured by
DeForest Radio Telephone & Telegraph Co.
Sales Office 101 Park Avenue,
New York.

Cable Address: Radiotel, N. Y.

"THERE IS ONLY ONE AUDION—THE DE FOREST."

The Audion Detector is the most sensitive detector in existence. The Bulletin of the U. S. Bureau of Standards, Vol. 6, No. 4, Page 540, states that it is fully 50 per cent. more sensitive than any other known form of detector. It is the only reliable sensitive detector.

For the benefit of those amateurs who desire to experiment, and who do not wish to buy complete Audion Detectors with the necessary accessories, and for those whose limited means will not permit the complete instruments to be purchased, we have brought out the Type T Tubular Audion Bulb.



Commencing March 15th, 1916, this type of Audion will be sold separately, without the other parts necessary for a complete Audion Detector. It is licensed for amateur use only and is NOT interchangeable with the regular round Audion Bulbs.

This type of Audion Bulb gives very loud response to signals. Every bulb passes two tests by our experts and is thoroughly up to our standard of sensitive qualities. It is finished in only one grade—the best.

The life of the Type T Tubular Bulb is exceptionally long on account of the fact that the single straightline filament has no loops, and as there is no second filament, the Edison discharge to same is completely eliminated.

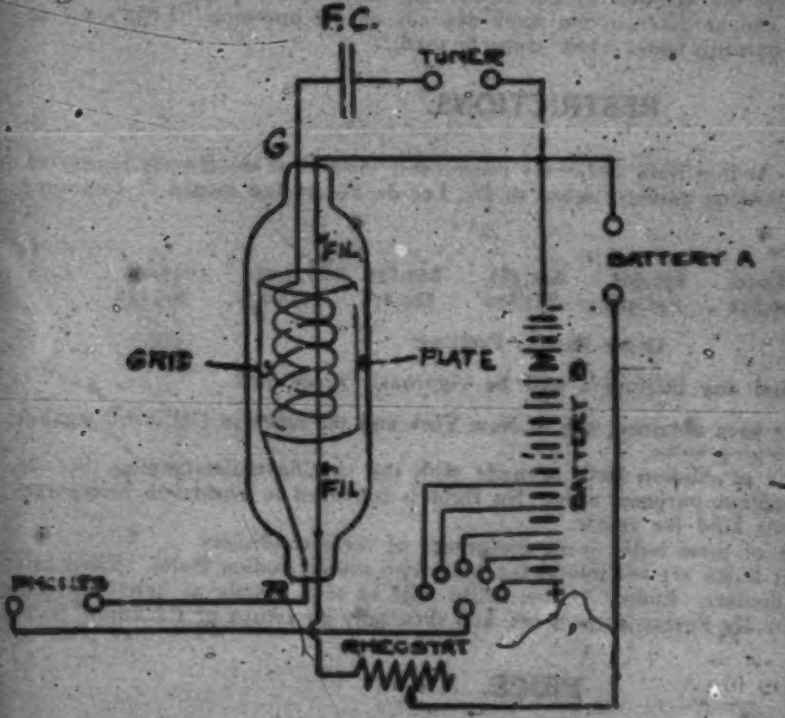
The plate or wing is in contact with the glass, preventing overheating. The filament is surrounded by a spiral grid.

This type of bulb is an excellent oscillator for the reception of continuous waves, being different in this respect than round Audion Detector Bulbs.

The grid is the spiral inside the tube and is connected to the green covered wire. The plate is connected to the red covered wire. The filament terminals are the white covered wires.

DIRECTIONS FOR USING
THE TYPE T TUBULAR AUDION BULB.

1. The diagram below illustrates the various accessories needed with the bulb. The rheostat is an ordinary battery rheostat, furnished by electrical supply houses. Battery B consists of 10 three cell flashlight batteries, each showing at least 3½ volts on a *voltmeter*. They are connected in series, with zinc of one to carbon of the next, and so on throughout the series. It is very important that each shows at least 3½ volts to 4½ volts and that they are properly connected together, otherwise the results will be very poor. The negative or zinc end of this battery *must* lead to the filament.



A switch is to be arranged as shown to cut in 6, 7, 8, 9 or 10 batteries at will.

The fixed condenser F.C. consists of two sheets of tin foil 2 inches square, separated by a *mica* sheet. This *must* be of first-class construction and of small capacity. A *small* variable condenser may be substituted.

Battery A should be a 6 volt storage battery of at least 40 Ampere hours capacity. Two sets of dry cells, each having 4 cells may be arranged in parallel instead, but the storage battery is recommended.

CAUTION

Do not permit either of the filament wires to come in contact with any circuit or any metal part carrying current. This might connect it to the Battery B and burn out the filament. *No credit* can be offered for a bulb burned out from *any* cause.

2. The bulb *must* be operated in a vertical position to give best service.

3. Always turn in all resistance on the rheostat before lighting the filament. Batteries recuperate on standing idle and the increase of voltage might burn out the filament.

4. Adjust rheostat to give normal filament brilliancy and adjust Battery B switch to best point. Then try reversing current from the lighting battery to find out which direction is better.

5. The bulb is most sensitive at a point just below that at which the hissing sound is heard in the telephones.

6. The receivers should be each of at least 1000 ohms resistance.

7. FOLLOW THESE DIRECTIONS TO THE LETTER. They are important.

GUARANTEE.

We guarantee the Type T Tubular Audion Bulb to have been tested by our expert and to have passed our standard which is fully 50 per cent more sensitive than any crystal or electrolytic detector, when leaving our factory.

We guarantee these bulbs to arrive in good condition. If a tubular Audion Bulb is broken in transit when shipped by us, and is returned *at once*, it will be replaced.

We will *not* replace any bulb for any other reason, whether due to breakage on account of negligence on the part of the operator or due to burning out of the filament.

No guarantee of life can be given as too much depends on the operator. Tests show an average life of over 800 burning hours when properly used.

RESTRICTIONS.

This and every other Audion Bulb and every conceivable method of using same is covered by one or more of the following patents, issued to Dr. Lee de Forest and owned or controlled by this company.

824,637	836,070	837,901	841,387	867,877	879,532	943,696
824,638	836,071	841,386	867,876	867,878	979,275	995,126

Other Patents Pending.

All and any infringers will be vigorously prosecuted.

Two injunctions have been obtained, one in New York and the other in California against makers and users of infringing bulbs.

The sale of this type of Audion Bulb is made with the specific understanding that the bulb is to be used for amateur purposes only. No right is conveyed to anyone to incorporate this bulb in any set of any kind for resale.

The purchase of one of these bulbs is an acceptance of these conditions.

The Type T Tubular Bulbs are not interchangeable with round Audion Bulbs. Their sale is entirely separate and distinct. Round Audion Bulbs will be sold exactly as heretofore, for renewal purposes only for De Forest instruments, and then only on return of De Forest Bulbs of similar type.

PRICE.

The price of the Type T Tubular Audion Bulb only is $5.50. The adapter to fit it to a screw socket will be furnished at 40 cents extra. It is not necessary to return the burned out bulb for renewal.

This Bulb and our other receiving equipment is furnished by 45 distributors conveniently located throughout the country. Name of nearest distributor furnished on request.

Write for Bulletins on Audion Detectors, Amplifiers and Receiving Sets if interested.

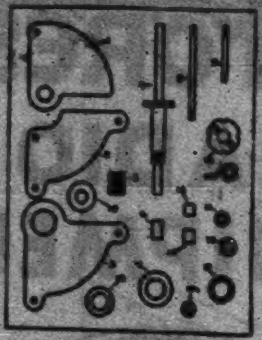
Knock-down Condenser Parts



Complete sets of parts for CV-500 Condenser .0005 Mfd. Price, $3.00 *Code Word:* LAMBESER. *Shipping Weight:* 1 pound.

The numbers in parenthesis refer to diagram. The other numbers to number of parts required:

(1) 12 Rotor plates (2) 13 Stator plates (3) 2 End plates (4) 1 Shaft (5) 2 End bearings (6) 3 Large filler posts (7) 4 Insulating collars for lock nuts (8) 3 Stator plate rods (9) 1 Rotor plate rod (10) 4 End lock nuts (11) 38 Stator separators (12) 2 Hard rubber collars (13) 3 Round tie rod nuts (14) 3 Small filler posts (15) 12 Large rotor separators (16) 2 Small friction washers (17) 2 Flat washers (18) 1 Rotor nut (19) 11 Rotor separators (20) 5 Hex nuts (21) 2 R. H. Brass screws (22) 1 Flexible charade wire.

Radio Frequency Transformers for Reflex Sets

The Transformers illustrated are sold singly or in sets for use in the Reflex circuit. These are laboratory precision parts, made with the care characteristic of all De Forest equipment. They are numbered to indicate the position in the circuit. Price, $2.50 each.

REFLEX
FREQUENCY TRANSFORMER

De Forest Combination Detector Amplifier Audions— Type DV-6 Vacuum Tubes

This new tube is of the metallic vapor operates without injury from 2½ to 6 volts dry batteries or storage batteries. It may with any standard circuit and in any type of ing apparatus without any change in wiring tube is as near a universal one as it is pos obtain. It functions with equal efficiency tector or an amplifier of audio frequency. It possible to use this tube successfully in ra quency circuits. It has small elements, there capacity, which is a very desirable feature fo frequency work.

These tubes are so called "hard" or gas because of this they are stable in their op They are excellent oscillators and have suffic put so that they may be used as radio frequen erators for measuring purposes. The filame sumption is small being approximately 2.8 wa depending on the use to which the bulb is put operated as a detector, the filament current than when operating as an amplifier. It is recommended that 40 volts be used on the plate when this tube is used as a detector and 40 to 60 volts when used as an amplifier. When working with a fully charged storage battery, never turn the rheostat on full. This tube should never be operated with more than five volts on the filament:

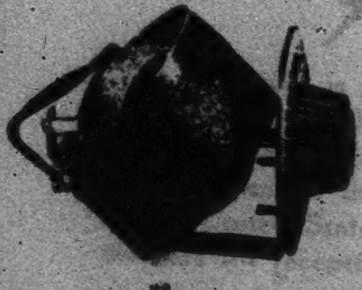
Filament 5 Volts; 5/10 of an ampere.

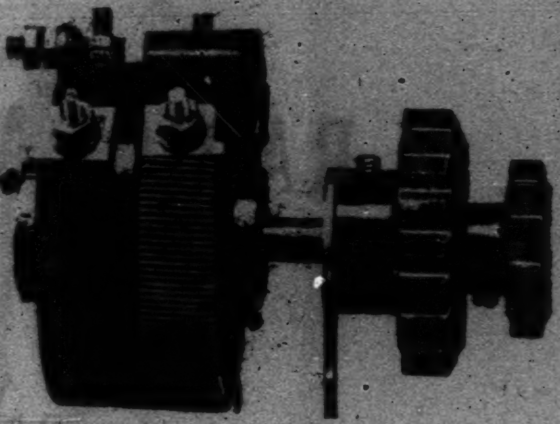
Plate Voltage, 40 to 60 Volts. Price $6.00.

Code Word: **Anda** *Shipping Weight:* **8 ozs.**

De Forest VL 180° Variocoupler Unit

This variocoupler is similar to that which has given such universal satisfaction in the De Forest D-7-A Reflex Receiver. It has twice the tuning efficiency of a 90 degree coupler, and quantity production has made it possible to sell this high quality laboratory tested product at a lower price than this type usually commands. Its wavelength range is 150 to 700 meters; it takes up only the amount of panel space necessary for its three inch dial; all metal parts are of brass, heavily nickel plated; solid Bakelite Dilecto XX grade tubing and silk covered wire are used throughout. Supplied with bracket and screws for either panel or table mounting; flexible leads provided for connecting to switch points. Advantageously used in connection with De Forest Type S-600 Variable B Battery switch. Price complete with Bakelite knob and dial, $3.75.





Combination Rheostat and Potentiometer Type RP-500

Unusual conservation of panel space and ease of control is afforded by this combination, on one moulded base with double knob control, of our F-500 standard rheostat and our P-1 potentiometer. Made also as RP-600, combining our F-600 power rheostat with the P-1 potentiometer, on common Bakelite mounted base, with concentric two-knob control. Price of either combination instrument, $2.00.

Made with the precision characteristic of all De Forest parts.

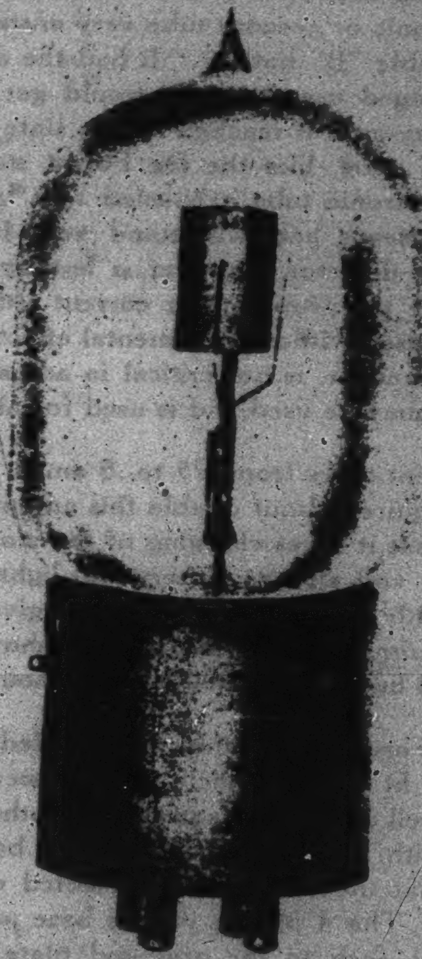
SEPTEMBER 1919

THE NEW DE FOREST "VT" AUDION



This tube is identical with the latest forms of tubes manufactured by the De Forest Radio Tel. & Tel. Co. for war work and is similar in shape to the VT-21 tube of which the De Forest Company made thousands for the Signal Corps during the war. In the United States its sale is restricted to amateurs and experimenters for reception only.

The tube consists of a highly evacuated vessel cylindrical, rather than bulbular, in shape enclosing the three elements, grid, plate and filament in the form of the old type T tubular De Forest tube with which amateurs are familiar. The plate is of nickle, cylindrical in shape and surrounds a helical grid also of nickle. The filament is a crimped tungsten wire passing through the center of the grid exactly as it did in the old style T type De Forest tube.

The chief difference between this tube and the type T tube of similar mechanical construction is in its evacuation. The old style type T was an ionic or gaseous tube very unstable in operation and requiring a variable "B" battery. It had the decided disadvantage that after continued use the tube would get "hard" and require more "B" battery until it reached such a state as to be inoperative. The new "VT" tube, like the De Forest standard tubes to-day, is purely an electronic tube exhausted to a very high vacuum, so that it is nongaseous and will stand very high plate potentials. When used as a detector, however, a battery of 20 to 40 volts is sufficient to give the proper plate current although voltages of 80 to 100 may be used without detrimental effect upon the tube. The "B" battery moreover, is not critical in adjustment and, therefore, a fixed battery may be used and is used for all practical work.

The filament takes from .75 to .8 amps. only, whereas the old type T tube required about double this amount. This is a decided advantage in that it saves charging of the storage batteries at short intervals. A 4 volt storage battery will light the filament, but a 6 volt battery with a control rheostat will give better results. The filament is of crimped tungsten and tests show that the majority of these tubes will burn from 1000 to 2000 hours.

The De Forest "VT" tube is provided with the standard 4-prong base to fit the receptacle on all recent types of De Forest apparatus as well as apparatus put out by other concerns. The base is provided with a pin which fits into a bayonet lock in the receptacle, so that the tube may be inserted or removed by merely a slight twist. The 4 prongs on the base are connected, 2 to the filament and 1 each to the grid and plate. These prongs mesh with springs in the bottom of the receptacle and in this way perfect connection is made to the receiving apparatus without the use of awkward flexible leads, binding posts, etc.

Amateurs are warned that the only tube available on the market at present is the De Forest "VT" tube above described. All other tubes advertising an outside plate or outside grid are humbugs sold to get around the De Forest patents and are absolutely worthless from an operative point of view.

De Forest "VT" Audion **Price $7.00 each**

INSTRUCTIONS FOR USING THE DE FOREST AUDION

These instructions apply to the new type high vacuum tube such as was used by the U. S. Army and Navy and is at present being manufactured by the Moorehead Company exclusively for the De Forest Company under the latter's patents. The Marconi Company are sole distributors for us. The old type gaseous tube with the candelabra base can be used similarly, except that a variable "B" battery of from 20 to 50 volts is required. The gaseous type tubes are, however, no longer being manufactured.

The audion tube should not be inserted into its socket until the operator is definitely sure that the control rheostat is set at the point marked "Off" or with its full resistance in circuit.

A 6 volt storage battery should be connected to the binding posts on the audion panel marked "A Bat" making sure that the polarity is as indicated.

After the tube has been placed in the socket turn the rheostat up slowly until the filament burns with the brilliancy of a tungsten lamp. Connect a fixed battery of from 20 to 60 volts into the plate circuit and in series with the telephone receivers. If then the grid circuit is connected in the usual way (by means of the binding posts "RA"—"RE" found on all De Forest apparatus) to the tuner, the audion should be operative and signals should be received as the circuits are tuned to the proper wave lengths.

How to Get the Most Out of Your Radio Tubes—Most Economically

USERS of Radio sets are of two general classes—

> *—those who derive their pleasure from listening to continuously good radio, preferring not to concern themselves with the how and why of it.*
>
> *—and those who delve into the technicalities of radio construction and find pleasure or profit in the results of their own handiwork.*

Sooner or later, however, *all* who enjoy radio, whether layman or expert, will realize the importance of the results which can be obtained by renewing the life of vacuum tubes. And this is true because not only does the quality of radio reception depend upon the condition of tubes, but one of the heaviest items of a set's maintenance expense results from tube replacements.

The radio expert is already familiar with the simple process which renews the life of what is known as the thoriated filament types of vacuum tubes. This process is called Tube Reactivation. Filament reactivation of vacuum tubes is not a mystery beyond the layman's understanding, nor is it beyond his interest, because by tube reactivation he can be assured of getting the utmost in quality of reception and in length of service from his vacuum tubes, and at the same time save a large portion of his tube expense. These two advantages, therefore, should be well worth the few moments spent in learning how tubes can be quickly and thoroughly reactivated, and why the process can be repeated time after time.

What Are the Symptoms of Weakened Tubes?

The conditions which definitely indicate to the set owner that the tubes should be checked up immediately are those with which most set owners are already familiar, although they seldom understand the cause. Some of the most common difficulties are weak signals on distant stations, loss of volume on local stations, or general poor quality reception from all stations. Another indication of an impaired tube, or tubes, is found in the necessity of turning the filament current higher and higher in an effort to force the tubes to function as they originally did. This is an injurious practice, because it not only draws excessively on the A battery and pulls down the volume of the good tubes in the set, but the excessive filament voltage damages the tubes and speeds the hour when they become wholly inoperative.

It should be remembered that no radio set is better than its weakest tube. And no set will long continue to operate efficiently nor economically unless all of its tubes are given frequent tests, and reactivated when the evidences of deterioration appear. The process of reactivation or renewing the life of a vacuum tube filament is more simple than charging an A battery. Less time is required to do it. The result is more lasting, the cost much less.

Reactivate Tubes of the Thoriated Filament Types

The tubes found in most sets are of two types known as UV-201A and C-301A (large tubes) and UV-199 and C-299 (peanut tubes). In these tubes are three elements—the plate, the grid and the filament. Each of these elements has a very definite work to do, but most important is that of the filament. It is upon the *condition* of the filament that the functioning of the other elements depend. And what is more important, this condition largely controls the quality of reception that can be had from a receiving set.

Every time a tube is used the filament performs its work less efficiently than the time before. Indeed, from the very moment of its first use, the filament goes through a continuous process of change and deterioration until finally the tube becomes lifeless and fails to amplify. This falling off in tube efficiency may be abrupt under certain conditions, but usually it is so gradual that the user either wastes much time in looking elsewhere for his difficulties or discards his tubes altogether. *Nine out of ten of these discarded tubes could have been made to give many more months of good service by the process of reactivation.*

So, by a better understanding of the importance of the filament, just how it functions, and a knowledge of the method now offered to renew its life, home operators of sets may have good reception continuously and at a fraction of a tube cost heretofore necessary.

What Actually Happens to the Filament?

First, let it be understood that for a vacuum tube to operate at all its filament must give off electrons. This is technically known as "filament emission". As the filament emission becomes less and less the tube's ability to amplify diminishes and the quality of reception falls off in proportion. New tubes should possess high filament emission, but this constantly decreases according to the amount of use or abuse to which they are subjected. In the UV-201A, C-301A, UV-199 and C-299 types of tubes, the filament is made from a special tungsten wire in which a metal known as thorium has been combined. The filament is active only when there is a layer or coating of this thorium on the surface, and, as previously stated, the condition of this coating governs the amount of filament emission. Operating a set at too high filament voltage will destroy the coating quickly and result in rapid deterioration of the tubes; and even at normal voltage the filament usually deteriorates through continuous use. In either case, poor reception will eventually result.

When poor reception becomes apparent, too many set owners—those who are unfamiliar with the process of reactivating the thorium coating—discard one or more tubes because they have been long in use. Other owners, not equipped to properly test tubes, replace the tubes believing the discarded ones must be worthless. *Nothing could be farther from the truth.*

A thoriated filament tube should not be declared "dead" simply because it fails to give the required amount of amplification. So long as the thoriated filament tube will burn, reactivation seldom fails to restore it. By the Sterling method of controlling the process of reactivation, the renewal of such tubes to their original amplification values may be made a certainty, and may be repeated over and over.

How It Is Possible to Make Tubes Come Back to Life

The thoriated filament tube becomes weak or lifeless as the thorium disappears from the surface of its filament. It is obvious that if the coating of thorium could be restored to the surface of the filament the tube would again be capable of amplification. This seemingly impossible result can be easily accomplished with the proper equipment. Inside the filament there remains a considerable supply of thorium and this is what makes recuperation possible, not only once, but repeatedly.

By the use of a simple and inexpensive electrical device, the STERLING REACTIVATOR, it is found that by burning the filament for a very short time at a high temperature followed by a lower temperature for a longer period, the thorium molecules are brought to the surface of the filament where a new thorium layer is formed. Thus, the amplifying ability of a seemingly exhausted tube is restored to its original strength. Some tubes have been successfully treated as many as seventy-five times with the Sterling Reactivator.

The Sterling Metered Instrument Takes the Guesswork Out of Tube Reactivation

Unless some means is provided for first actually testing a tube's emission, also for retesting to determine its increase in emission during and after a treatment, then tube reactivation becomes an uncertain process.

(1) When does a tube need reactivation?
(2) Is emission improving during treatment?
(3) What is its filament emission afterward?

Because of the importance of these three questions, the Sterling is provided with a FILAMENT EMISSION METER which removes all doubt as to what the reactivator accomplishes. For example, if, when a UV-201A tube is inserted in the Sterling instrument, the emission meter shows a reading lower than 20, reactivation is necessary. This test can be made instantly simply by moving a lever. Very often tubes will be found in which the filaments are slow to respond to reactivation, yet are capable of much higher emission than will be shown after one short treatment. For example, if the meter indicates only 30 to 40 after the tube has been in the instrument for the prescribed time, the "Low" or "Test" voltage generally results in increasing the emission. Without the meter in the instrument for checking the emission, the need of a second treatment would many times not be apparent, and even if it were tried the user would not be *certain* that he had increased the tube's amplification ability in the least.

Moreover, without an emission meter it is impossible to match tubes—to group them of approximately equal filament emission. In fact, without a meter the determination of the relative filament emission of tubes, to obtain the best reception from a set, is no more than a matter of guess-work. With the Sterling metered instrument results are *observed*, *controlled* and known to be *definite*.

Reactivate Tubes Only When a Filament Emission Test Shows They Need It

Reactivating tubes at regular periods without first testing them to determine the amount of filament emission present, is *not* recommended. Unless the filament needs reactivation, the process has the tendency to shorten the useful life of the tube. It is good practice, however, to check emission frequently to insure good amplification, also to be certain that one or more tubes are not being operated at too low efficiency, and that tubes are not being blamed for other possible defects in the receiving set.

The filament emission meter used in the Sterling instrument is a unique feature, essential to intelligent treatment of tubes and to accurate results. By its use, treatment of most thoriated filament tubes may be repeated many times with the result that the tubes will give their original amplification after being reactivated. Complete Instructions for operating are attached to the bottom of each instrument.

Sterling R-403 Tube Reactivator is just as essential to the proper care and use of vacuum tubes as is the battery charger to the battery. It is built with the same care that has for more than fifteen years made every Sterling electrical product worthy of its name.

Letter and Data Sheets Furnished by Witness Kelly.

October 28, 1926

Dear Mr. Hogan:

In the preparation of this data two slight errors were detected. The pressure for Exhibit 32 should be about one-half that previously given. The actual slope of the lower line for 9.111 should be a little steeper.

These matters will be alluded to (so I understand) in my further examination this morning.

M. J. KELLY.

8 sheets of data herewith.

PROBABILITY OF IONIZATION OF GAS MOLECULES BY ELECTRON IMPACTS

BY

K. T. COMPTON AND C. C. VAN VOORHIS

Reprinted from PHYSICAL REVIEW, pp. 436-453, Vol. 26, No. 4, October, 1925

PROBABILITY OF IONIZATION OF GAS MOLECULES BY ELECTRON IMPACTS

By K. T. Compton and C. C. Van Voorhis

Abstract

Ionization in various gases by electrons of energy 0-325 volts.—Electrons from a hot filament were projected through an ionization chamber B containing gas at low pressure (.001 to .005 mm) and into a trap. Positive ions produced in B were collected on fine wires arranged in the form of a squirrel cage C and maintained at a potential lower than B by an amount V_r. Corrections were made for the facts (1) that the wires C lowered the potential at the center of B and hence retarded the electrons passing through B by a maximum amount of $0.4\times V_r$, and (2) that if V_r was numerically less in value than the accelerating potential V_a, some primary electrons reached C. The pressures were measured with a McLeod gauge to 1 percent and were corrected for the heating effect of the filament, which was determined by using the apparatus as an ionization manometer to be about 26°. The resulting curves for N, the number of ions per cm path produced by an electron moving through a gas at 1 mm pressure, are believed correct within a few percent. In agreement with previous results of Hughes and Klein and others, the curves each rise to a maximum. The maximum values found and the corresponding voltages are as follows:

	H_2	He	Ne	A	N_2	Hg	HCl
N(max):	3.55	1.65	3.2	10.33	9.96	19.44	17.3
V(max):	145	210	340	140	178	135	130
P(max):	0.29	.209	.254	.466	.423	.239	.558

The values for P(max), the corresponding probability that a collision will result in ionization of the hit molecule, were computed from N(max) assuming the kinetic theory values for electronic mean free paths. These results are compared with previous experimental values. Ionization was found to begin at the ionizing potential in each case, except that with N_2 weak ionization was observed at 10 volts. This may possibly be associated with the presence of traces of active nitrogen.

TOWNSEND'S original theory of ionization by collision[1] assumed that ionization of a gas molecule occurs whenever it is struck by an electron whose speed exceeds the minimum ionizing speed, but this theory led to values of the minimum ionizing speed which were considerably in error. Bergen Davis[2] and one of the writers[3] modified Townsend's theory by assuming that the relation between the energy V of an electron at impact and the probability P that ionization of the molecule results from the impact is given by $P=(V-V_i)/V$ when $V>V_i$ and $P=0$ when

$V<V_i$. This assumption led to calculated values of the minimum ionizing energy V_i which agreed better with the true values than did Townsend's original theory, but which were still incorrect. The recent advances in the study of various types of electrical discharge through gases, and especially the development of Langmuir's[4] new method for determining the distribution of velocities of the electrons in an ionized gas, have emphasized the importance of accurate knowledge of the values of the probability P of ionization by electron impacts at various speeds and in various gases.

The first experimental observations of this sort were made by Lenard[5] and were extended under his guidance by Kossel[6] and Mayer.[7] These investigators found that the probability of ionization is zero for impact energies up to the minimum ionizing potential, then increases to a maximum of less than 0.5 at impact energies of about 150 volts, followed by a decrease as the energy is further increased up to 1000 volts.

The present investigation was designed to introduce a number of refinements in technique, so as to permit the maximum possible accuracy of the observations. Shortly after we had begun, Hughes and Klein[8] published results of a research on the same problem, in which a considerable number of gases was tested over a large range of electron impact energies. In general features and in order of magnitude our present results agree with the findings of these and of the earlier investigators. We believe, however, that the present method permits greater accuracy of observation and reliability of interpretation than the methods previously used, so that we felt justified in continuing the work to its present conclusion.

The general procedure in such work is to accelerate electrons from a photo-electric or thermionic source and project them into a region in which the products of ionization are collected by a subsidiary system of electrodes. Besides obvious precautions of accuracy, calibration, gas purity, etc., there are several inherent difficulties encountered in endeavoring to measure the ionization per electron per unit path through the gas. The first of these is due to the fact that the electrode system which collects the products of ionization is subject also to charge arising from photo-electric action on the electrodes by radiation excited by electron impacts in the gas. The second difficulty is due to the necessity of applying a field in the region between the collecting electrodes in order to draw to them the products of ionization and to prevent any of the primary ionizing electrons from reaching these electrodes. Because of this field, the primary electrons do not pass through the gas with a constant speed, but with speeds which vary from that with which they are projected into the ionizing region down to much smaller values (down to zero in the experiments of Hughes and Klein). It is, therefore, impossible to say to just what energy of impact the observed ionization should be ascribed, and it is necessary to compute the desired result by setting up an integral equation to represent the observations and to solve it by differentiating the experimental curve. To the above difficulties might be added a third source of error which arises from any ionization of a cumulative type or from more than one impact by the same primary electron.

In the present work we have eliminated the first and third of these difficulties and reduced the second so that the value for the ionization per electron per centimeter path is set experimentally within rather narrow limits and may be computed within these limits with but a small probable error.

APPARATUS AND ITS USE

The apparatus employed is shown in Fig. 1. The filament F consisted of a few turns of 10 mil (.25 mm) molybdenum wire, in front of which was placed a focusing ring connected to the negative terminal. The narrow tube T through the bottom of the shielding box served to direct a narrow beam of electrons into the middle region of the chamber B. The positive ions formed in B were attracted to the collector C, which consisted of five 20 mil wires supported at each end by a ring of the same sized wire. The use of small wires for collecting the positive ions had the triple advantage of reducing to an inappreciable value the photo-electric current from this electrode, of reducing the chance that primary electrons which might be scattered in the gas would reach this electrode, and of reducing the effect on the velocity of the primary electrons due to the collecting field V_r. The ion trap S served to catch the electrons after passing through B, and also any positive ions produced after passing through the gauze at the bottom of B. The chamber B was 2.8 cm long and about 3 cm in diameter. All metal parts were made of nickel except the filament, and were freed from gas by heating in vacuo to a red heat by high frequency induction currents.

The electrical connections used in making the measurements are shown in Fig. 2. The variable accelerating voltage was measured by a voltmeter V_a, while G_- and G_+ measured, respectively, the electron current I_- into the chamber B and the positive ion current I_+ resulting from ionization by the electrons passing through the gas in this chamber. We thought, when beginning the investigation, that a magnetic field produced by a current through a coil wound around the glass jacket and

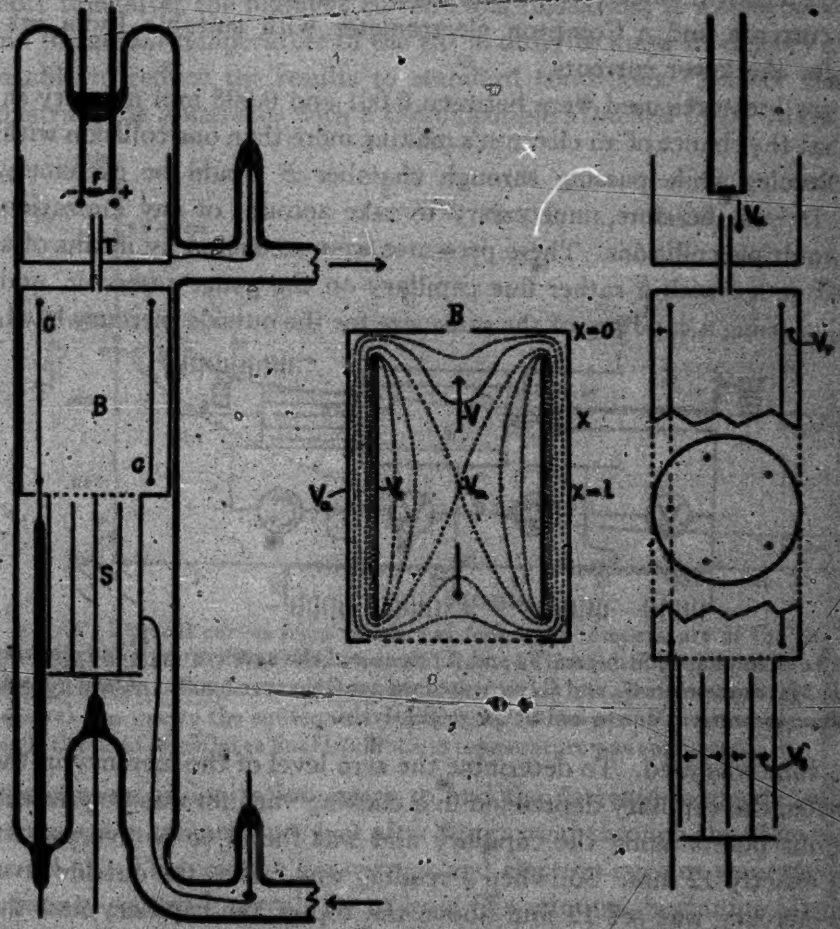

Fig. 1. Electrons from the filament F were projected through the tube T into the ionization chamber B in which the products of ionization were collected by a "squirrel cage" arrangement of wires C. The non-colliding electrons passed into the ion trap S. The dotted curves represent equipotential surfaces, with an axial point of minimum potential V_m, when the potentials of B and C are V_a and V_c, respectively, with respect to the filament.

coaxial with the chamber B would prevent electrons from reaching the collector C and thus permit us to use so small a collecting field as not appreciably to affect the speed of the primary electrons passing through the chamber. When this plan was tried, however, it was found that the ratio of I_+ to I_- for any given pressure was very irregular, being subject to small variations in the magnetic field, and that these irregularities could be shifted from lower to higher voltages by increasing the magnetic field. Not succeeding in explaining or eliminating this effect of the magnetic field, we abandoned its use and applied a retarding voltage V_r to the collector C to prevent electrons from reaching it. A galvanometer with a sensitivity of about 300 megohms was used as G_-, while for G_+ were employed a galvanometer of about 11000 megohms sensitivity for the higher currents and a Compton electrometer with suitable India ink shunts for the lower currents.

The gas pressures used were between 0.001 and 0.005 mm mercury in order that the chance of an electron's making more than one collision with gas molecules while passing through chamber B would be extremely small. It was, therefore, unnecessary to take account of any ionization due to multiple collisions. These pressures were measured by means of a McLeod gauge with a rather fine capillary on the gauge reservoir, and instead of using a capillary of the same size for the outside mercury level, a 1 cm tube was used. To determine the zero level of the mercury in the 1 cm tube, the capillary depression in a clicking vacuum was determined at various points along the capillary and was found to be everywhere almost exactly 12 mm. So, when a reading was taken, the outside level of the mercury was set 12 mm above the top of the capillary and the pressure read off the calibration curve as usual. The capillary tube was always tapped with a pencil while the mercury was coming to equilibrium in the tubes, to avoid any error due to the adhesion of the mercury to the walls. Also, parallax was avoided by observing the level of the mercury in the capillary through a lens mounted at the end of one edge of a small square. With these refinements the readings of the pressures varied less than 1 percent for different settings on the same pressure. A further check on the accuracy of the pressure readings was made occasionally by finding the product of the length of the gas-filled capillary times the difference in level of the mercury columns (the 12 mm capillary depression being de-

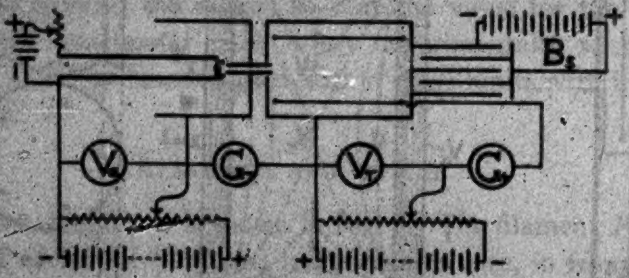

Fig. 2. Circuits. Voltmeters V_a and V_r measured the accelerating and collecting fields, and galvanometers G_- and G_+ measured the total electron current entering B and the positive ion current due to ionization, respectively.

ducted of course) for different levels of the mercury in the capillary. This check was used whenever there seemed to be any pronounced sticking of the mercury in the capillary near the level used in the regular method of reading.

Determination of gas temperature. Since the chamber *B* became warm a short time after the filament current was turned on, it was necessary to find the actual temperature of the gas in order to know its density and to be able to reduce the results to standard conditions. Rather than reconstruct the apparatus with a thermocouple attached to *B*, we used the apparatus as an ionization gauge to find the decrease in gas density due to increase in temperature just after the current through the filament was turned on. The positive ion current and electron current were measured at twenty second intervals for at least five minutes, beginning about one minute after the filament current had been turned on, and then at less frequent intervals until stable conditions were reached. Fig. 3 shows the results of two typical runs in mercury vapor, one with $V_a = 160$ volts and the other with $V_a = 320$ volts. The ordinates are numbers of positive ions produced per electron in traversing the length of *B*, per 0.001 mm pressure of the vapor.[9] The values of this number at time 0, i.e., at room temperature, are obtained by a short extrapolation of the curves back-

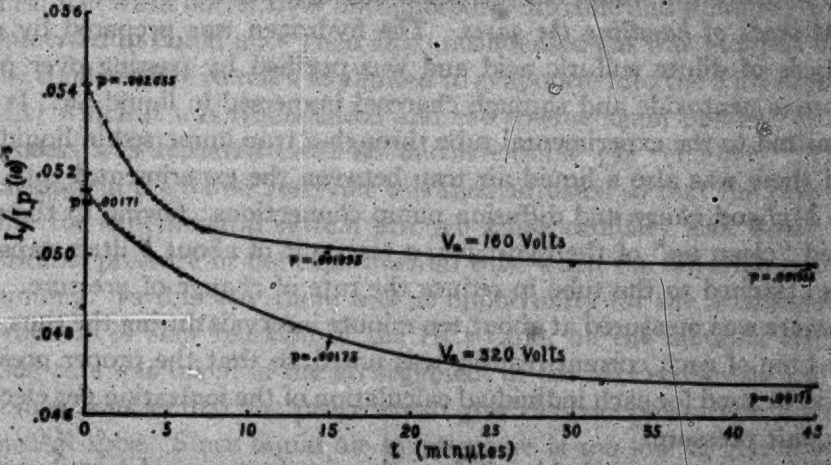

Fig. 3. Typical curves from which was found the temperature of the gas in the ionization chamber *B*. Time was measured from the instant of turning on the filament heating current. The decrease in ordinate (ionization per electron per 0.001 mm gas pressure) was due to the subsequent warming up of the gas. By use as an ionization gauge, the ratio of initial to final equilibrium temperature was computed.

---

[9] The difference in the shape of these curves is due, for the most part, to the differences in initial pressures and in changes of pressure during the runs. That is the reason for giving the pressures in the figure.

ward. Thus with $V_a=160$ volts the final ordinate is 91.9 percent of the initial one, and corresponds to a temperature rise of 26° above the room temperature of 25°; and with $V_a=320$ volts the final ordinate is 90.7 percent of the initial one and corresponds to a temperature rise of 30° above the room temperature of 23°. From the consideration of nine such runs, it was decided that 51°C best represents the temperature of the gas in chamber *B* throughout the various observations. The possible variations from this temperature would not introduce any appreciable error.

Methods of handling the gases. The hydrogen was prepared by electrolysis of dilute sulfuric acid and was purified by passing over phosphorous pentoxide and through charcoal immersed in liquid air. It was admitted to the experimental tube through a trap immersed in liquid air, and there was also a liquid air trap between the experimental tube and the McLeod gauge and diffusion pump connections. Owing to the very rapid "clean up" of the hydrogen, a reservoir of about 5 liters capacity was attached to the tube to reduce the rate of change of pressure. The pressure was measured at about ten minute intervals during the runs, and the time of each current reading was noted, so that the proper pressure could be used for each individual calculation of the ionization per electron per unit pressure.

The argon was purified by prolonged arcing between calcium electrodes and was admitted to the experimental tube through a liquid air trap. To insure the purity of the neon and the helium in the tube, a charcoal trap, a tube containing copper and copper oxide, and a high pressure diffusion pump were added to the system in such a way that the gas could be circulated by the pump through the glowing copper and copper oxide and the charcoal, which was immersed in liquid air. This circulation was not continued while observations were being made, since the action of the circulating pump caused somewhat erratic variations in the gas pressure within the experimental tube. The helium and neon were each spectroscopically free from each other before being admitted to the system.

The nitrogen first used was generated by the reaction of sodium nitrite and ammonium chloride, stored in contact with phosphorous pentoxide and admitted through a tube immersed in liquid air. After finding that some ionization set in at about 10 volts (see Fig. 5) it was thought that possibly there might be some nitrogen oxides present, so that other runs were made using nitrogen generated by the action of bromine on ammonia and stored over phosphorous pentoxide—a method which is supposed to yield very pure nitrogen.[10] However, the experimental results with the gas prepared by the two methods were almost identical.

---

[10] Waran, Phil. Mag. 42, 246 (1921).

While making the observations on mercury vapor, the liquid air was removed and the pressure varied for different runs by varying the room temperature. The slight temperature changes during a run were taken account of by noting at ten minute intervals the temperature of a thermometer placed in the vicinity of the system, and the time of each current measurement was noted, as in the case of hydrogen.

For the observations on hydrogen chloride, the gas was generated by the action of sulfuric acid on hydrochloric acid, passed through a sulfuric acid wash bottle, over phosphorous pentoxide and solidified in a tube immersed in liquid air. Then any uncondensed gas was pumped off, and the condensed material was allowed to evaporate into the 5 liter reservoir, after which it was recondensed and the residue again pumped off. This process was repeated until no uncondensable gas remained. The gas pressure in the 5 liter reservoir was then adjusted so that the rate of flow into the experimental system through a fine capillary leak would give a suitable pressure in the experimental tube when the diffusion pump was running. In this way there was no opportunity for the accumulation of products of slow reaction of the HCl vapor on the metallic electrodes. Due care was taken in the arrangement of the McLeod gauge and pump connections so that the gauge would give the true pressure in the experimental tube. Since liquid air temperature is too low to give a suitable vapor pressure of hydrogen chloride, a temperature between 10° and 25° higher than liquid-air temperature was maintained in the traps for keeping out mercury vapor, by surrounding the traps with cylinders of brass closed at the bottom, these in turn being surrounded by large glass test tubes immersed in liquid air. By allowing about an inch of the brass cylinder to extend above the top of the liquid air flask, the pressure of the hydrogen chloride could be made as high as about 0.015 mm. Since there was usually a slight pressure change during a run, the same method of obtaining the correct pressure for each observation was used as in the cases of hydrogen and mercury vapor.

Potential at the center of chamber B. In order to prevent any appreciable number of electrons from striking the positive ion collector, V_p had to be made slightly larger than V_a. Thus the space through which the electrons passed within the chamber B was not field free, but had a potential distribution, probably such as shown in the central part of Fig. 1. The potential with respect to the filament would be a minimum at the center of B. Thus an electron, entering B with the speed corresponding to V_a, would be retarded until it reached the center, and then would be accelerated so that it would pass out of B with the same speed as that with which it entered, provided it suffered no inelastic collision on the way. Two methods were used in determining the potential at the center of B. The first consisted in measuring the total electron current I_- while V_a was kept constant and V_r varied, for a series of values of V_a both in a vacuum and in hydrogen. When I_- was plotted against V_r, a marked change in slope was found in every curve at a value of V_r about 2.5 times that of V_a. This critical value of V_r was interpreted as being the one above which electrons were turned back before reaching the center of B, some striking the tube T or the under side of the shield containing it. Therefore V_m, the potential at the center of B, may be taken as $V_a - 0.4|V_r|$, where $|V_r|$ represents the numerical value of the retarding potential applied between B and C.

The second method of determining V_m was to place a sensitive galvanometer in series with the 22.5 volt battery B (Fig. 2), connecting the two sets of vanes of the ion trap, and noting at what value of V_a, for a given V_r, electrons began getting through B into the ion trap. It was found that they began to get through when V_a was from 0.40 to 0.45 times $|V_r|$, thus confirming the conclusion that $V_m = V_a - 0.4|V_r|$, to a close approximation.

Methods of measurement and calculation. Series of measurements were made on all the gases investigated by noting G_- and G_+ as V_a was varied from below the minimum ionizing potential to about 320 volts (410 volts in the case of neon to make sure that the voltage for maximum I_+ had been passed) with $|V_r|$ always about 1.5 volts greater than V_a. Readings were taken at intervals of one volt to above twice the ionizing potential; then of two volts to about 100 volts; of five volts to about 180, and then of ten volts over the rest of the range. Preliminary tests showed that the ratio I_+/I_- was independent of the filament temperature, i.e., of I_-, over a wide range. For convenience, about the same filament current was used all through the investigation and the galvanometers were calibrated at the beginning and end of each individual run. Several runs were made at somewhat different pressures with each gas. The only limitations in the pressures and currents which could be used were (1) that these must be large enough to give sufficient ionization for accurate measurement, and (2) that they must not be so large as to allow appreciable ionization by cumulative action or by more than one impact by an electron.

From the readings of G_- and G_+, the galvanometer and electrometer calibrations and the gas pressures, the ratio $I_+/(I_-p)$, where p is the pressure of the gas in mm of mercury, was calculated. Then from the results of three or more such runs which agreed within 2 percent with one another over most of the range for each gas, the mean values of this ratio were found for each voltage V_m. When these mean values were plotted against the values of V_a they gave such curves as curve *a* in Figs. 4 and 5. The ordinates of this curve should give the average number of ionizing collisions made per electron while moving a distance equal to the length of B (2.8 cm) through the gas at 1 mm pressure with velocity corresponding to V_a, if it were not for the fact that the space within B is not field free and consequently the electrons do not all have the velocity V_a when they strike the gas molecules. Two methods were used to take into account this uncertainty, (1) by calculation based on the distribution of potential within B, and (2) a direct method whereby the desired quantity can be set by experiment between narrow limits.

First method. Of several assumptions made regarding the variation of potential along the path of the electrons in B, the one which gave the most reasonable results was the assumption that the potential varies at a uniform rate from the end to the center. Then the value of the potential V (with respect to the filament) at any point x in B is given by

$$V=V_a-\int_x^l Edx=V_a-E(l-x)\ ,$$

where l is the distance from the center to the end of B, x is the distance of the point x from the center of B and E is the electric intensity (supposed constant). At the center, $x=0$, hence

$$V_m=V_a-El=V_a-0.4(V_a-V_c)$$

where $V_c=V_a-|V_r|$ is the potential of the collecting electrode. Thus $E=0.4\ (V_a-V_c)/l$. Substituting this above, and remembering that V_c in our experiments was only 1.5 volts, we have approximately

$$V=V_a(0.6+0.4x/l)\ . \tag{1}$$

Let $M=I_+/(I_-p)$ stand for the observed ionization per electron per unit pressure in the chamber B. Let $f(V)$ be the average number of ionizing collisions made by an electron if it passed through B with uniform velocity of V volts, at unit pressure. Then we should have

$$M=\int_{V_m}^{V_a} f(V)d(x/l)\ .$$

Since $V_m=0.6V_a$, and differentiation of Eq. (1) gives $d(x/l)=(2.5/V_a)dV$, we have

$$M=(2.5/V_a)\int_{0.6V_a}^{V_a} f(V)dV\ .$$

By differentiation,

$$0.4\,d(MV_a)/dV_a=f(V_a)-f(0.6\,V_a)\ . \tag{2}$$

In applying this equation to determine $f(V_a)$ from the experimental values of V_a and M, we have two cases to consider:

If $V_a < 1.67$ times the minimum ionizing potential V_i, then $f(0.6\ V_a) = 0$, and we have

$$f(V_a) = 0.4\, d(MV_a)/dV_a\,. \qquad (3)$$

If $V_a > 1.67\ V_i$, then

$$f(V_a) = 0.4\, d(MV_a)/dV_a + f(0.6\ V_a) \qquad (4)$$

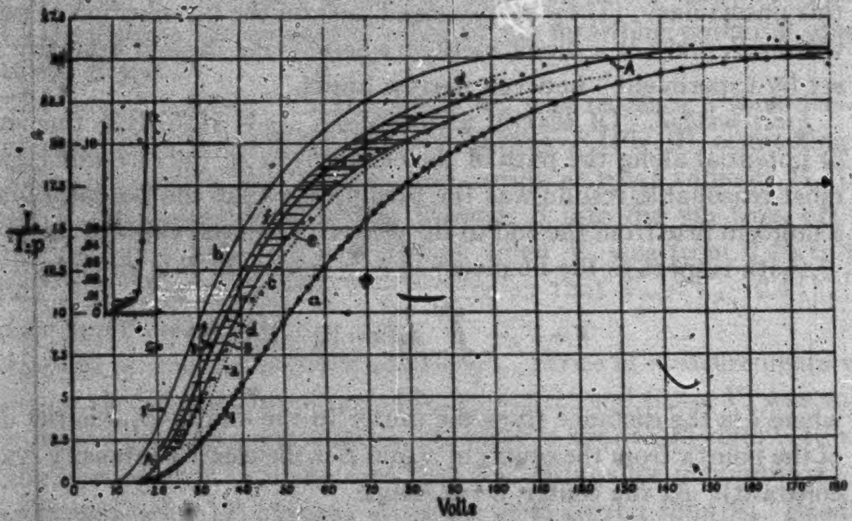

Fig. 4. Curves for nitrogen; positive ions formed per electron per mm pressure per 2.8 cm path as a function of energy of electrons, in volts. Curve *a* gives experimental results when $V_r = V_a + 1.5$ volts, thus with primary electrons prevented from reaching *C*. Curve *b* gives the same values plotted against the minimum energy V_m instead of the maximum energy V_a. The true curve lies between these. Curve *c* gives experimental values when V_r was adjusted for maximum ionization, and curve *d* gives the same for minimum voltage V_m. Curves *e* and *f* were obtained by correcting *c* and *d* for stray electron current. The true curve lies between *e* and *f* and is taken as curve *A*. Crosses are points which were computed from curve *a* by method (1).

The values of $f(V_a)$ were calculated for the different voltages used, by means of Eq. (3) and (4) and plotted at the mid-points $V_a - \frac{1}{2}\, dV_a$, giving results such as are shown by the crosses in Figs. 4 and 5. A rather marked change in slope was noted in all of the M curves at a value of V_a approximately twice the ionizing potential, and this break was still more pronounced in the $f(V_a)$ curves. It was at first suspected that these breaks might be due to ionization of highly excited molecules, or by the double ionization which might occur if a molecule, excited by an energy at least twice the minimum ionizing energy, should make a collision of the second kind with a neutral molecule. Such effects should, however, tend to disappear at very low gas pressures, whereas we found that the curves, including this break, were identical down to extremely low pressures. In the second method, described below, it was found that this break shifted according to the value of V_r, so that we are inclined to attribute it to a peculiarity of the field within B, due to lack of radial symmetry of the collecting electrode system. It probably indicates a second order error in the values of M and $f(V_a)$ in the lower voltage ranges.

The second method for finding the number of ionizing collisions which would be made by an electron moving with a uniform speed V_a through B in gas at unit pressure, can be best explained by referring to Fig. 4. Consider, for instance, the experimental reading marked 1. Here the electrons entered the chamber B with velocity of 36 volts and reached the center of B with velocity of 0.6 of 36, or 24 volts. The ordinate at 1 must therefore be the value of $f(V_a)$ corresponding to some value of V_a between 36 and 24 volts. In other words, the corresponding point on the $f(V_a)$ curve must be somewhere between 1 and 1′. Similarly for every point on curve *a* there is a corresponding point on curve *b* which is shifted to the left by an amount 0.4 of V_a. The true curve for $f(V_a)$ must lie between the curves *a* and *b*.

Now, by decreasing the field V_r to a value considerably less than V_a, keeping V_a constant at 36 volts, it was found that the current I_+ increased to a maximum value when V_r was 11 volts, and then decreased with further decrease in V_r. The reason for this is that decrease in V_r produced two opposing effects: (1) It diminished the retardation of the electrons, thus causing them to traverse B with speeds more nearly equal to V_a, and thus increased the ionization produced by them; (2) it permitted some electrons to reach the collecting electrode, and thus diminished the apparent amount of ionization. The observed value of I_+ corresponds to point 2 in Fig. 4. Owing to the electrons which reached the collecting electrode, the true ionization must have been somewhat greater than this. The amount by which it was greater was determined by making a similar measurement with the gas removed from the tube, so that the stray electron current only was measured, and this was checked by similar measurements in the gas at values of V_a less than V_i. Adding this to the current corresponding to point 2 gives the current which would have been observed with V_r equal to 11 volts, had there been no reverse current due to electrons. This ordinate at point 3 corresponds to electrons which entered B with velocity 36 volts, and whose velocity fell by 0.4 of 11 volts, or by 4.4 volts within B. Thus the ordinate is the value of $f(V_a)$ for some value of V_a between 36 and 31.6 volts. Thus the limits within which the value of $f(V_a)$ must lie have been much narrowed down; it must lie between points 3 and 4. A consideration of all the factors involved led to the choice of point 5 as the most probable point, and it is certain that this value of V_a and $f(V_a)$ cannot be in error by more than a few percent. In this way, the values of $f(V_a)$ were found and plotted as curve A, which lies between the experimentally fixed limits shown by curves e and f.

Of the two methods, the second is the more reliable in that it does not depend on any assumption regarding the distribution of potential within B. The agreement between the two methods is indicated by the way in which the crosses are distributed with respect to the experimental limits

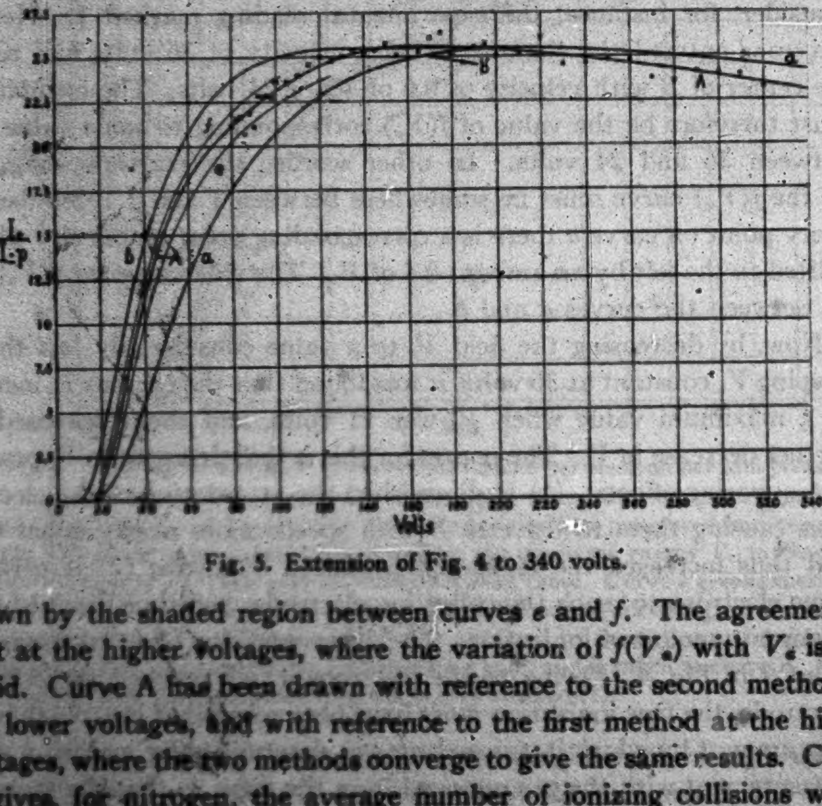

Fig. 5. Extension of Fig. 4 to 340 volts.

shown by the shaded region between curves e and f. The agreement is best at the higher voltages, where the variation of $f(V_a)$ with V_a is less rapid. Curve A has been drawn with reference to the second method at the lower voltages, and with reference to the first method at the higher voltages, where the two methods converge to give the same results. Curve A gives, for nitrogen, the average number of ionizing collisions which would be made by an electron moving with constant speed V_a through chamber B containing the gas at 1 mm pressure. Fig. 5 shows the same results, continued to the higher voltage ranges.

DISCUSSION OF RESULTS

If the values of the ordinates of curve A are divided by the length of the chamber B, they give the average number N of ionizing collisions per electron per cm path per mm gas pressure as a function of the velocity. The assembled results of our experiments are shown in Fig. 6, where N

stands for the quantity defined just above. It is of interest to note that the value of N continues to decrease with still greater electron speeds. For air, according to Kossel[6] N decreases from about 10 at 200 volts to 3.3 at 1000 volts, 0.4 at 30,000 volts and 0.18 for β-rays.

The probability P of ionization at an impact may be found by dividing these values of N by the number of collisions per cm path made by an electron moving through the gas at 1 mm pressure. Although there is some uncertainty regarding the true values of this number, the experiments of Ramsauer[11] and Mayer[12] indicate that the ordinary kinetic theory value of electronic mean free path is at least approximately correct at speeds as large as those in which we are interested, except for argon at the lower speeds. We shall, therefore, assume that the electronic mean free path equals $4\sqrt{2}$ times that of the gas molecules. The values are given

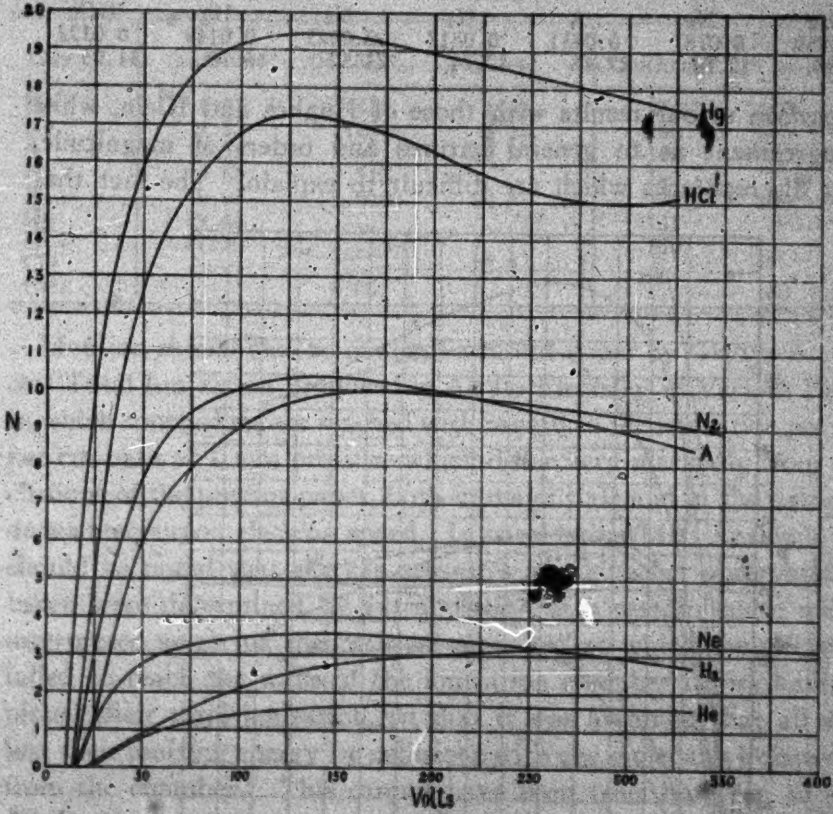

Fig. 6. Number of positive ions formed per electron per cm path through gas at 1 mm pressure, as a function of the electron energy in volts.

A comparison of our results with those of Hughes and Klein, while showing agreement as to general features and orders of magnitude, brings out discrepancies which are difficult to explain. The fact that their values are consistently smaller than ours may be due to the fact that they appear not to have taken account of the heating of the gas in the apparatus by the filament. We feel that their results are definitely too low, since they fall below the lower limit set by curves, such as curve *s* of Figs. 4 and 5, which are the direct result of measurement and depend on no calculations or assumptions, but only on the calibration of the gal-

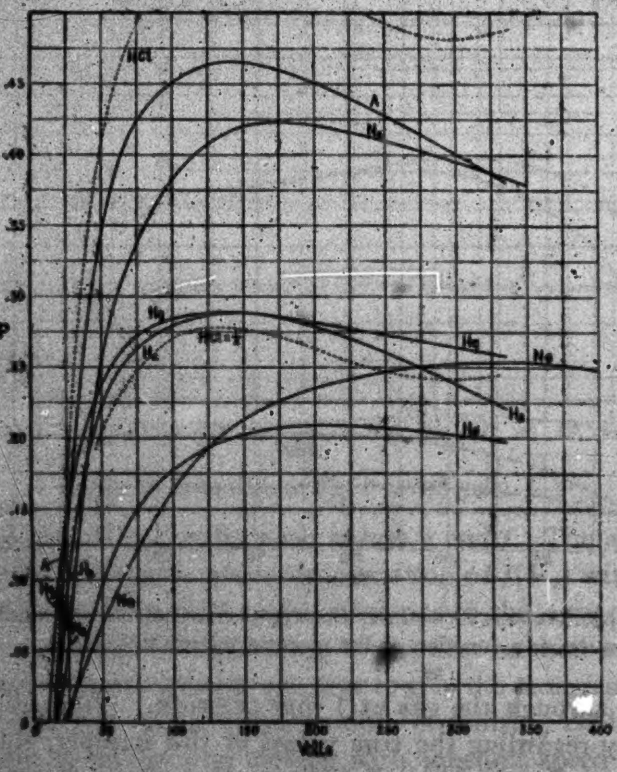

Fig. 7. Probability of ionization at an impact as a function of the electron energy in volts, assuming kinetic theory values of electronic mean free paths.

vanometers and the McLeod gauge. Some aspects of this comparison are shown in Table II. This table also contains values from a recent paper by Jesse.[13] Although he does not claim much accuracy for his absolute values of N, his results agree more closely with ours than do those of Hughes and Klein.

TABLE II

Gas	N(max) (authors)	N(max) (H. & K.)	N(max) (Jesse)	V_e(max) (authors)	V_e(max) (H. & K.)	V_e(max) (Jesse)
He	1.65	0.881	1.61	210	150	140
Ne	3.22	1.828	3.16	340	160	220
A	10.33	7.65	14.5	140	80	100
H_2	3.55	2.518	.....	145	73.5	...

CO	.....	.....	12.8	...	.....	120
CH_4	.....	8.06	.....	...	80	...

Mention should also be made of a recent paper by Gladys A. Anslow[14] on "Total Ionization Produced in Air by Electrons of Various Energies," in which conclusions are reached with regard to the ionization per electron per cm path at 1 mm pressure which differ very markedly from the conclusions of the present paper, both in magnitude and in the nature of the dependence upon electron speed. In considering Miss Anslow's work, it should be noted that the gas pressures at which her observations were taken were determined by extrapolation of a certain curve which was interpreted as giving the "critical pressure" at which the electrons just failed to reach the walls of the ionization chamber before having completed their total ionization, so that it was assumed that all electrons lost their ionizing energy by collisions with gas molecules before escaping from the chamber. This cannot have been true, however, as a simple calculation based on electron mean free paths shows. For all of her voltages below 1000 volts, an appreciable number of electrons would have traversed the ionization chamber without having collided at all; below 300 volts the majority would have thus escaped collision, while at the maximum of her curve, Fig. 6, not more than one percent of the electrons would have collided. Thus the interpretation of the results at the lower voltages is incorrect and these results cannot be taken as inconsistent with the results of the present paper. Incidentally, we believe that the maximum in Miss Anslow's Fig. 6 is due to the combination of the variation in the number of electrons which collide and the variation of the probabilities of ionization at the different pressures and voltages used.

[13] W. P. Jesse, Phys. Rev. 26, 208 (August, 1925).

[14] Gladys A. Anslow, Phys. Rev. 25, 484 (1925).

On the basis of measurements with the ionization gauge, Dushman[15] suggested that the ionization in different gases is proportional to the total number of electrons in the molecules of the gases. The present results do not support this suggestion as a quantitative relation. It may be, however, that the proposed relation is more accurate at higher voltages than those at which we worked—as might be expected on theoretical grounds and as is indicated by the early work of Kossel,[16] who made the same suggestion on the basis of measurements at 1000 volts.

Finally, the apparent ionization of nitrogen at about 10 volts (see Fig. 4) raises an interesting question of interpretation. As shown in the insert, this is extremely weak as compared with the ionization setting in at the ordinary ionizing potential. Three possibilities present themselves: (1) It may represent a weak and hitherto undiscovered type of ionization of nitrogen; (2) it may be due to photo-electric effect on the collecting electrode C by radiation excited in the gas; (3) it may be due to electron emission from the collecting electrode C produced by contact with "excited" or "active" molecules of nitrogen. In opposition to the second suggestion is the fact that in no other gas was there any detectable current which could be ascribed to photo-electric effect; the scheme for eliminating complications from this cause seemed to be quite successful. In favor of the third suggestion is the fact that this observed critical potential agrees well with the internal energy of at least one type of active nitrogen, which has been placed at 9.52 volts by Saha and Sur,[16] as revised by Foote, Ruark, and Chenault.[17] If this is the correct interpretation, the detection of the active nitrogen by an apparatus relatively insensitive to the photo-electric effects would be due to the greater probability of electron emission at a collision of the second kind between an excited molecule and the metal than by photo-electric action of radiation. If this be true, it must still be remarked that the efficiency of these low voltage impacts in producing active nitrogen must be quite small, else Duffendack would have detected it in his low-voltage arcs.[18] We hope later to be able to give a definite answer to this question.

Note added with proof. Further consideration of the work by Hughes and Klein[8] and by Jesse[11] indicates that in both cases the assumed values of primary electron current must be in error. The former are too large, owing to an incorrectly assumed linear relation between current and field on one side of the grid. The latter are too small on account of neglect of

secondary electrons which subtract from the primary electron current. Experiments are being undertaken to see whether these corrections are adequate to account for the discrepancies in the three experiments on this subject. It may be noted that in the present work both the ionization and the primary electron currents were measured directly, and that secondary electrons were avoided by use of the electron trap.

ARNOLD

HAROLD DeFOREST ARNOLD, in the County of New York, State of New York, being duly sworn, deposes and says:

I am one of the parties to the interference declared by the Commissioner of Patents on August 8, 1916, between my application for Letters Patent for Thermionic Devices and Method of Constructing and Operating the Same, filed November 2, 1915, and an application of Irving Langmuir.

I conceived the invention set forth in the declaration of interference and disclosed the same to others in the latter part of 1912.

The first written records evidencing invention were made on various dates in the latter part of 1912 and at frequent intervals thereafter, and the first drawing illustrating the invention was made on March 24, 1913.

The invention was reduced to practice on December 26, 1912 and again on March 24th, and April 25th of 1913.

Since the date of reduction to practice, the invention has been used in wire and wireless telephonic communications carried on by the American Telephone and Telegraph Company and the Western Electric Company, Incorporated, both in experimental and commercial work.

(signed) HAROLD DeFOREST ARNOLD.

Sworn to and subscribed before me this 1st day of September, 1916.

In the preliminary statement of Arnold the allegations with respect to conception, disclosure and written description are too indefinite. The exact day and month in 1912 when these acts took place should be set forth.

Arnold is given until September 18, 1916, within which to file an amended statement overcoming these objections. For failure to so amend he will be restricted to December 31, 1912, for conception, disclosure, and first written description.

vs.
LANGMUIR } Interference No. 40,380

COMMISSIONER OF PATENTS,
Washington, D. C.

Sir:

Referring to the order of the First Assistant Commissioner, January 11, 1917, the following additional particulars are now given in regard to the citation of articles appearing on page 6 of Arnold's Supplementary Motion to Dissolve:—

The article in Annalen der Physik, Vol. 28, pages 537-552 (1909), comprising sixteen (16) pages, is considered to be of importance and will be relied upon.

The entire articles of Majorani published in Atti Della Reale Accademia dei Lincei, Vol. 21, pages 235-239 inclusive, and in the same publication, pages 274-277 inclusive, are considered to be of importance and will be relied upon. These articles comprise respectively five pages and four pages.

The article by Fleming in the Proceedings of the Royal Society, January 1905, pages 476-487 inclusive comprises twelve (12) pages, three pages of which are given up to tables, and all of this article is considered to be of importance.

The article by McClelland in Proceedings of Cambridge Philosophical Society, Vol. 10, (1900), page 241, is hereby withdrawn from consideration.

The address by Dewar before the Royal Institution of Great Britain, June 7, 1907, published in Engineering, Vol. 83, page 781, June 14, 1907, is all comprised on one page.

The article in the Sitzungsberichte der Physicalisch Medischen Gesellschaft, Vol. 37, pages 312-315 (1905), comprises only four pages, all of which are pertinent and should be considered.

Respectfully,
(signed) D. C. TANNER,
Attorney for Arnold.

UNITED STATES PATENT OFFICE

To all persons to whom these presents shall come, Greeting:

THIS IS TO CERTIFY that the annexed is a true copy from the records of this office of Letter to Office, filed February 8, 1918, in the matter of

Interference Number 40, 380,

ARNOLD VS. LANGMUIR,

Subject Matter:—

Electric Discharge Apparatus and the Process of Preparing the Same.

[SEAL] IN TESTIMONY WHEREOF I have hereunto set my hand and caused the seal of the Patent Office to be affixed, at the City of Washington, this fourteenth day of September in the year of our Lord, one thousand nine hundred and twenty-six and of the Independence of the United States of America the one hundred and fifty-first.

THOMAS E. ROBERTSON,
Commissioner of Patents.

ATTEST:
D. E. WILSON,
Chief of Division

IN REPLY ADDRESS
THE SECRETARY OF THE NAVY
AND REFER TO NO.

40380—85

NAVY DEPARTMENT
WASHINGTON

VR/WSS/26840

February 7, 1918.

From: Secretary of the Navy
To: Commissioner of Patents, Washington, D. C.

SUBJECT: Case of Arnold v. Langmuir, No. 40,380.

1. Both Dr. Arnold and Dr. Langmuir are engaged in important work for the Navy Department.

2. The case of Arnold v. Langmuir was postponed for a period of six months because of this fact. Both of these gentlemen are still actively engaged practically for a great majority of their time and, if it can be consistently done, it is requested that a further extension of six months in the taking of testimony be granted.

3. It is understood that both of these gentlemen and their counsels will be glad to agree to this extension if you can see fit to grant it.

F. W. ROOSEVELT,
Acting

PLAINTIFF'S EXHIBIT No. 201.

Exhibit.

OPTION.

AGREEMENT made this Sixteenth day of December, 1912, between PETER COOPER HEWITT, of New York City, and the AMERICAN TELEPHONE AND TELEGRAPH COMPANY, a New York corporation, hereinafter called the Telephone Company.

In consideration of the sum of Thirty Thousand Dollars ($30,000.), paid by the Telephone Company to the said Hewitt, the receipt of which is hereby acknowledged, the said Hewitt agrees for himself, his legal representatives and assigns, as follows:

1. If, within one year from the date hereof, the Telephone Company pays to Hewitt One Hundred and Ten Thousand Dollars ($110,000) in addition to the amount mentioned above, and executes and delivers to Hewitt agreements in the forms A and B hereto attached (excluding some of the patents therein mentioned or referred to, if the Telephone Company so elects), Hewitt will thereupon execute (and cause the Cooper Hewitt Electric Company to execute) both of said agreements, (and the Westinghouse Cooper Hewitt Company, Limited, to execute Agreement B,) in the form delivered by the Telephone Company, and also duplicate originals thereof, and will deliver to the Telephone Company such executed duplicate originals.

2. Hewitt will not object to the Telephone Company making and using, for purposes of experiment, test and demonstration, C. H. T. devices, as defined in attached agreements, embodying or containing or operating in accordance with the inventions referred to in the attached form of license up to the date of exercise of said option by the Telephone Company, but not beyond a period of one year from the date hereof, if said option is

not exercised within said period; and Hewitt will make no claim against the Telephone Company, or those operating under its authority, because of such making and using.

If the said option is exercised, the Telephone Company, its successors and assigns, may continue to use and may sell or lease to others for use and sale, or rental, the apparatus made during the option period, upon paying $30 per installation, as provided in the attached form of license.

3. Hewitt warrants that he has full power and authority to grant this option and to enter into the license agreement hereto attached, and that he has not made and will not make any agreement in conflict herewith or with his ability to execute and carry out the provisions of the attached license agreement.

IN WITNESS WHEREOF, the said Hewitt has executed this instrument the day and year first above written.

(Signed) Peter Cooper Hewitt.

The Cooper Hewitt Electric Company, holding the legal title to some of the patents referred to in the foregoing option and attached form of licenses hereby, upon behalf of itself and on behalf of the Westinghouse Cooper Hewitt Company, Limited, which also holds the legal title to some of the said patents, all of the capital stock of which Company, is held and owned by the Cooper Hewitt Electric Company, acknowledges to and agrees with the American Telephone and Telegraph Company that so far as concerns the Cooper Hewitt Electric Company and the Westinghouse Cooper Hewitt Company, Limited, or others claiming under it or them, the above mentioned Peter Cooper Hewitt has full right and power to grant the foregoing option and to enter into the attached license agreements A and B, and the Cooper Hewitt Electric Company to the same extent hereby ratifies and confirms the foregoing option and the attached license agreements upon its own behalf and on behalf of the Westinghouse Cooper Hewitt Company, Limited, and it agrees that it and said last mentioned Company will execute said agreements when requested so to do by the said Peter Cooper Hewitt.

State of New York, } ss.:
County of New York. }

On this Sixteenth day of December, 1912, before me personally came CHARLES B. HILL and CHARLES A. TERRY, to me known, who being by me severally duly sworn did depose and say; the said Charles B. Hill that he resides in Montgomery, New York; that he is Vice President of the Cooper Hewitt Electric Company, the corporation described in and which executed the above instrument; the said Charles A. Terry that he resides in New York City; that he is the Secretary of the said corporation; that they know the seal of said corporation; that the seal affixed to said instrument are such corporate seal; that they were so affixed by order of the Board of Directors of said corporations, and that they signed their names thereto by like order.

(Signed) ROBERT FOSTER JAMES,
Notary Public, etc.

PLAINTIFF'S EXHIBIT No. 201-A.

Agreement A.

UNITED STATES LICENSE.

AGREEMENT made this day of 191 , between PETER COOPER HEWITT of New York City and the AMERICAN TELEPHONE and TELEGRAPH COMPANY, a New York Corporation, herein called the Telephone Company.

WHEREAS, the said Hewitt has made many inventions, among which are those set forth in the following patents of the United States:

No. 749,791, dated January 19, 1904,
No. 749,792, dated January 19, 1904,
No. 749,793, dated January 19, 1904,
No. 758,650, dated May 3, 1904,
No. 781,001, dated January 31, 1905,
No. 781,002, dated January 31, 1905,
No. 954,434, dated April 12, 1910,
No. 991,304, dated May 2, 1911,

and

WHEREAS, said enumerated patents and other patents for the inventions of said Hewitt were assigned to the Cooper Hewitt Electric Company, a New York corporation, under certain agreements dated March 7, 1900 and November 7, 1902, between the said Hewitt and George Westinghouse, but the said Hewitt retained under said agreements and now owns, for himself and his assigns, the exclusive rights under all of said patents for certain uses, among which is their use for C. H. T. devices as hereinafter defined; and

WHEREAS, the Telephone Company desires a license to utilize said inventions in such apparatus as hereinafter set forth;

Now, in consideration of the mutual agreements herein contained, it is agreed as follows:

1. Hewitt hereby grants to the Telephone Company the right and license to make or cause to be made for it and to use gas or vapor electric apparatus for creating, transmitting or receiving or relaying or repeating or amplifying or boosting telephonic or telegraphic electric currents, waves or impulses in telephone or telegraph systems employing wires or metallic conductors connecting stations (all of which devices are, for convenience, herein called C. H. T. devices), embodying or made or operating in accordance with any and all inventions which he has heretofore made, and to sell or lease such C. H. T. devices to others and to license them to sell, use or lease the same, which license shall continue to the end of the terms of all patents of the United States which have been or may be obtained on inventions which have been made by Hewitt up to the present date for which applications for United States patents shall have been filed prior to two years from the date hereof.

The foregoing licenses are granted and agreed to be granted for and throughout the United States of America and its territories and dependencies, and shall be exclusive (subject to the provisions hereinafter contained) in the field of telephony and telegraphy using wires or metallic conductors connecting stations on land lines, including communication over sub-aqueous cables, such as extend through rivers, lakes and seas, and to the immediate outlying land, and shall be non-exclusive for trans-oceanic cable lines; nothing herein shall prevent Hewitt from granting to others rights under his inventions to use C. H. T. devices in trans-oceanic cable lines at intermediate landing points, nor from granting to others the right to make C. H. T. devices for such uses.

2. Hewitt further agrees that as and when, up to January, 1921, he hereafter makes inventions useful in or applicable to C. H. T. devices, he will endeavor to promptly and fully disclose the same to the Telephone Company, and each such invention shall come under this agreement, if the Telephone Company so elects from time to time within one year after the date of each such disclosure. If the Telephone Company does so elect, the Telephone Company shall have, with reference to such inventions, the licenses above expressed to the end of the terms of the United States patents to be granted upon the several inventions so disclosed and brought under his agreement. If Hewitt or the Cooper Hewitt Electric Company does not desire to file and prosecute applications for United States patents upon any such inventions so disclosed to the Telephone Company, Hewitt shall give the Telephone Company an opportunity of filing and prosecuting the same. If the Telephone Company elects to prosecute the same, Hewitt agrees to execute all proper papers in connection therewith and assign to the Telephone Company the invention and United States patents to be issued for the same, the Telephone Company agreeing to grant to Hewitt, free of expense, rights under

said patents for uses in fields other than those of telephony and telegraphy in a broad sense as defined in the last paragraph of this Clause 2.

The Telephone Company agrees that when and if it makes commercial installations of C. H. T. devices embodying any inventions under which this license is granted, it will, up to January 19, 1921, give to Hewitt, but not to his assigns or representatives the opportunity of examining the same and witnessing the operation thereof. Information received by Hewitt from or through the Telephone Company or its interests shall be utilized by Hewitt in his discretion in the interest of the Telephone Company and not to the detriment of that Company.

The Telephone Company further agrees that it will give to Hewitt, but not to his assigns or representatives, an opportunity of acquiring a right to use and of granting to others the right to use any improvements which the Telephone Company may make in C. H. T. devices embodying inventions under which this license is granted, such rights being limited, however, to users for other than telephony or telegraphy in a broad sense, namely, including transmission over conductors on land or transoceanic cables or wireless transmission. Such rights may be acquired by Hewitt on terms to be agreed upon from time to time; it is recognized that no basis for such acquisition can be fixed at present; but the understanding is that Hewitt shall have an opportunity of acquiring such rights or of purchasing such apparatus from the Telephone Company at a fair price, and at a price at least as low as any price, acceptable to the Telephone Company, offered by others.

3. The Telephone Company agrees that it will keep books showing the manufacture of said C. H. T. devices by or for it, and the installations of such apparatus made by it or under its authority, which books shall at all reasonable times be open to the inspection of Hewitt or his duly authorized agents.

An "installation" is defined as an apparatus employed to create, transmit, receive, relay, repeat, amplify or boost electric currents, waves or impulses in a circuit or between lines connected or interconnected to form a circuit for transmission of sounds or signals, whether a one-way or two-way working apparatus, and without regard to the number of tubes employed or the particular circuit arrangement of connections, provided, however, that

(a) if the apparatus employed in a given connection or circuit is located at two or more places separated by outside line construction, the apparatus in each such location shall be counted as a separate installation;

(b) If a circuit divides into several branches not reuniting, and independent apparatus is installed in more than one branch of the circuit, then each such apparatus shall count as a separate installation, even although not separated from the others by outside line construction;

(c) if there should be employed apparatus capable of operating simultaneously for several independent circuits, although using one or more parts in common, such apparatus shall be considered as a number of installations equal to the number of independent circuits upon which it is arranged to work simultaneously.

4. The Telephone Company agrees that it will on or before the twentieth day of each January and July, during the term of this agreement, render to Hewitt a statement in writing setting forth the number of installations of C. H. T. devices (embodying or operating in accordance with any of the inventions under which this license is granted, leased, sold or put into use by it or under its authority in the six calendar months immediately preceding that in which each such statement is rendered.)

The Telephone Company further agrees that, subject to the provisions hereinafter contained, it will, at the time of rendering each such statement up to January 19, 1921, the date of expiration of said patents Nos. 749,791 and 749,792, pay to Hewitt an amount in royalties equal to Thirty Dollars ($30) for each such installation so reported. After said date the royalty shall be Ten Dollars ($10) for each additional installation embodying the invention of any unexpired patent or patents in force at the time of each such installation.

Royalties are payable only with reference to installations as above defined and not on tubes or other parts for replacement or renewal, nor upon the same apparatus when transferred to a new location or to other circuits.

5. If the royalties paid under this license with reference to the year 1914 and each year thereafter up to and including 1920 do not amount to at least as much as Ten Thousand Dollars ($10,000) for each year, and the Telephone Company does not, at the time of ren-

dering the statement for the last half of any such year, pay an amount which, added to the royalties then due, brings the total payments for the year up to said sum, Hewitt may, by notice in writing delivered to the Telephone Company on or before March 1 of the year following that for which the payments have been less than said sum, change the exclusive license, herein granted, to a non-exclusive one.

6. If the Telephone Company fails to render statements and pay the royalties due as and when stated above, and fails to repair its default within sixty days after the receipt of written notice thereof from Hewitt, Hewitt may cancel and terminate this agreement by serving on the Telephone Company written notice of his election so to do.

7. In case at any time or times, during the continuance of this license, any of the patents under which this license is granted, are being infringed by the use of apparatus within the field of telegraphy and telephony covered by this license, then the Telephone Company shall have the right to cause a suit or suits for infringement to be brought and prosecuted under such patent at its own cost and expense using the name of Hewitt or the Cooper Hewitt Electric Company, or both, if it so desire. If the attorneys employed by the Telephone Company for prosecuting the suit shall be unsatisfactory to the said Hewitt or to the Cooper Hewitt Electric Company, in case the latter has an interest in such patent, he or it may employ an attorney to take part in the prosecution of the case.

If any patent with reference to which royalty is payable hereunder is held to be invalid by any Court of final jurisdiction or by any inferior Court from whose decree no appeal is taken and prosecuted within the time prescribed by law, the Telephone Company shall thereafter be under no obligation to pay royalties with reference to such patent. If the patent is held to be valid but limited in scope, the Telephone Company shall thereafter be under no obligation to pay royalties with reference to its utilization of the C. H. T. devices or method of operation held not to be covered by such patent.

8. Hewitt warrants that he has full right to grant the licenses and make the agreements herein set forth, and that he has not made and will not make any agreement in conflict herewith.

9. Hewitt agrees that he will, at any time or times on request of the Telephone Company, execute and deliver to the Telephone Company such further or other instruments as the latter may desire for fully vesting in it the license and rights herein conveyed.

10. It is agreed that the recognition of the validity of patents, arising out of the acceptance of this license, is limited to their validity in connection with C. H. T. devices as herein defined.

11. This agreement and license shall be binding upon and shall inure to the benefit of the parties hereto, and their several successors, legal representatives and

assigns. The Telephone Company's rights hereunder shall not be assignable or transferrable except to an assignee or transferee who shall agree in all respects to be bound by the obligations of the Telephone Company hereunder; and Hewitt agrees that he will cause any assignee or transferee of his rights hereunder or of his patents under which this license is granted, to be bound by all of his obligations as expressed herein.

IN WITNESS WHEREOF, Hewitt has executed this instrument and the Telephone Company has caused this instrument to be executed by its proper officers thereunto duly authorized, on the day and year first above written.

AMERICAN TELEPHONE AND TELEGRAPH COMPANY,

By ____________________

Attest:

____

Secretary.

The Cooper Hewitt Electric Company referred to in the preamble of the foregoing license hereby acknowledges and agrees with the American Telephone and Telegraph Company that, so far as concrns itself or others claiming under it, the above-mentioned Peter Cooper Hewitt has full right and power to grant the licenses and to make the agreements set forth in the foregoing instrument, and it hereby, to the same extent, ratifies and confirms the granting of the licenses and the said license agreement.

COOPER HEWITT ELECTRIC COMPANY,
By

Attest:
Secretary.

State of New York, County of New York, } ss.:

On this day of , 191 , before me personally came PETER COOPER HEWITT, to me known and known to me to be the individual described in and who executed the foregoing instrument, and he acknowledged to me that he executed the same.

Notary Public.

United States License.

AGREEMENT made this fifteenth day of December, 1913, between PETER COOPER HEWITT, of New York City and the AMERICAN TELEPHONE AND TELEGRAPH COMPANY, a New York corporation, herein called the Telephone Company.

WHEREAS, the said Hewitt has made many inventions, among which are those set forth in the following patents of the United States:

No. 749,791, dated January 19, 1904,
No. 749,792, dated January 19, 1904,
No. 749,793, dated January 19, 1904,
No. 758,650, dated May 3, 1904,
No. 781,001, dated January 31, 1905,
No. 781,002, dated January 31, 1905,
No. 954,434, dated April 12, 1910,
No. 991,304, dated May 2, 1911,

and

WHEREAS, said enumerated patents and other patents for the inventions of said Hewitt were assigned to the Cooper Hewitt Electric Company, a New York corporation, under certain agreements dated March 7, 1900, and November 7, 1902, between the said Hewitt and George Westinghouse, and an agreement, dated December 31, 1912, was entered into between said Hewitt and the Cooper Hewitt Electric Company, a New Jersey corporation (both of the Cooper Hewitt Electric Companies being hereinafter referred to as the Cooper Hewitt Electric Company, the New Jersey Company being the successor of the New York Company), but the said Hewitt retained under said agreements and now owns, for himself and his assigns, the exclusive rights under all of said patents for certain uses, among which is their use for C. H. T. devices as hereinafter defined; and

WHEREAS, the Telephone Company desires a license to utilize said inventions in such apparatus as hereinafter set forth:

Now, in consideration of the mutual agreements herein contained, it is agreed as follows:

1. Hewitt hereby grants to the Telephone Company the right and license to make or cause to be made for it and to use, in telephone or telegraph systems employing wires or metallic conductors connecting stations, gas or vapor and so called vacuum electric apparatus for creating, transmitting, receiving, relaying, repeating, modifying, amplifying or boosting telephonic or telegraphic electric currents, waves or impulses, or (in so far as not in conflict with the agreements above referred to) for lightning arresters, or strong current discharger or protector, or charge or voltage limiters, embodying or made or operating in accordance with any and all inventions which he has heretofore made either alone or jointly with others (all of which devices are, for convenience, herein called C. H. T. devices), and to sell or lease such C. H. T. devices to others and to license them to sell, use or lease the same, which license shall continue to the end of the terms of all patents of the United States

which have been or may be obtained on inventions which have been made by Hewitt up to the present date for which applications for United States patents shall have been filed prior to two years after the date hereof.

The foregoing licenses are granted and agreed to be granted for and throughout the United States of America and its territories and dependencies, and shall be exclusive (subject to the provisions hereinafter contained) in the field of telephony and telegraphy using wires or metalic conductors connecting stations on land lines, including communications over sub-aqueous cables, such as extend through rivers, lakes and seas, and to the immediate outlying land, and shall be non-exclusive for trans-oceanic cable lines; nothing herein shall prevent Hewitt from granting to others rights under his inventions to use C. H. T. devices in trans-oceanic cable lines at intermediate landing points and terminals, nor from granting to others the right to make C. H. T. devices for such uses.

2. Hewitt further agrees that as and when, up to January, 1921, he hereafter makes inventions, useful in or applicable to C. H. T. devices, he will, upon filing application for patent for any such invention, endeavor to promptly and fully disclose the same to the Telephone Company and deliver to the Telephone Company a copy of such application, and each such invention made by him alone shall come under this agreement (and likewise his interest in those made jointly with others), if the Telephone Company so elects from time to time within

one year after the date of each such disclosure. If the Telephone Company does so elect the Telephone Company shall have, with reference to such inventions, the license above expressed to the end of the terms of the United States patents to be granted upon the several inventions so disclosed and brought under this agreement. If Hewitt or the Cooper Hewitt Electric Company does not desire to file and prosecute applications for United States patents upon any such invention hereafter made, Hewitt shall disclose the same to the Telephone Company, and give the Telephone Company an opportunity of filing and prosecuting the same. If the Telephone Company elects to prosecute the same, Hewitt agrees to execute all proper papers in connection therewith and to assign to the Telephone Company the invention and United States patents to be issued for the same, the Telephone Company agreeing to grant to Hewitt, free of expense, rights under said patents for uses in fields other than those of telephony and telegraphy in a broad sense as defined in the last paragraph of this Clause 2.

The Telephone Company agrees that when and if it makes commercial installations of C. H. T. devices embodying any inventions under which this license is granted, it will, up to January 19, 1921, give to Hewitt, but not to his assigns or representatives, the opportunity of examining the same and witnessing the operation thereof. Information received by Hewitt from or through the Telephone Company or its interests shall be utilized by Hewitt in his discretion in the interest of the Telephone Company and not to the detriment of that Company.

The Telephone Company further agrees that it will give to Hewitt, but not to his assigns or representatives, an opportunity of acquiring a right to make, use and sell, and of granting to others the right to make, use and sell any improvements which the Telephone Company may make in C. H. T. devices embodying inventions under which this license is granted, such rights being limited, however, to manufacture, sale and use for other than telephony or telegraphy in a broad sense, which "broad sense" here includes transmission over conductors on land and trans-oceanic cables and wireless transmission. Such rights may be acquired by Hewitt on terms to be agreed upon from time to time; it is recognized that no basis for such acquisition can be fixed at present; but the understanding is that Hewitt shall have an opportunity of acquiring such rights or of purchasing such apparatus from the Telephone Company at a fair price, and at a price at least as low as any price, acceptable to the Telephone Company, offered by others.

3. The Telephone Company agrees that it will keep books showing the manufacture, lease and sale of said C. H. T. devices by or for it, and the installations of such apparatus made by it or under its authority, which books shall at all reasonable times be open to the inspection of Hewitt or his duly authorized agents.

An "installation" is defined as an apparatus employed to create, transmit, receive, relay, repeat, modify, amplify or boost electric currents, waves or impulses in a circuit or between lines connected or interconnected to form a circuit for transmission or sounds or signals, whether a one-way or two-way working apparatus, and without regard to the number of tubes employed or the particular circuit arrangement or connections, or employed as a lightning arrester, or strong current discharger or protector, or charge or voltage limiter in telephone or telegraph systems, provided, however, that

(a) if the apparatus employed in a given connection or circuit is located at two or more places separated by outside line construction, the apparatus in each such location shall be counted as a separate installation;

(b) if a circuit divides into several branches not re-uniting, and independent apparatus is installed in more than one branch of the circuit, then each such apparatus shall count as a separate installation, even although not separated from the others by outside line construction;

(c) if there should be employed apparatus capable of operating simultaneously for several independent circuits, although using one or more parts in common, such apparatus shall be considered as a number of installations equal to the number of independent circuits upon which it is arranged to work simultaneously.

4. The Telephone Company agrees that it will, on or before the twentieth day of each January and July, during the term of this agreement, render to Hewitt a statement in writing setting forth the number of installations of C. H. T. devices (embodying or operating in accordance with the inventions of any unexpired patent or patents under which this license is granted,

and in force at the time of each such installation), leased, sold or put into use by it or under its authority in the six calendar months immediately preceding that in which each such statement is rendered.

The Telephone Company further agrees that, subject to the provisions hereinafter contained, it will, at the time of rendering each such statement, pay to Hewitt an amount in royalties to be computed in accordance with Schedule A hereto attached, for each such installation so reported.

Each sale of C. H. T. devices for an installation shall, for the purpose of royalty payments, be considered to be an installation whether or not actually installed at time of sale and royalty shall then accrue.

Royalties are payable only with reference to installations as above defined and not on tubes or other parts for replacement or renewal, nor upon the same apparatus when transferred to a new location or to other circuits.

5. If the royalties paid under this license with reference to the year 1914 and each year thereafter up to and including 1920 do not amount to at least as much as Ten Thousand Dollars ($10,000) for each year, and the Telephone Company does not, at the time of rendering the statement for the last half of any such year, pay an amount which, added to the royalties when due, brings the total payments for the year up to said sum, Hewitt may, by notice in writing delivered to the Telephone Company on or before March 1 of the year fol-

lowing that for which the payments have been less than said sum, change the exclusive license, herein granted, to a non-exclusive one.

6. If the Telephone Company fails to render statements and pay the royalties due as and when stated above, and fails to repair its default within sixty days after the receipt of written notice thereof from Hewitt, Hewitt may cancel and terminate this agreement by serving on the Telephone Company written notice of his election so to do.

7. In case at any time or times, during the continuance of this license, any of the patents under which this license is granted, are being infringed by the use of apparatus within the field of telegraphy and telephony covered by this license, then the Telephone Company shall have the right to cause a suit or suits for infringement to be brought and prosecuted under such patent at its own cost and expense using the name of Hewitt or the Cooper Hewitt Electric Company, or both, if it so desires. If the attorneys employed by the Telephone Company for prosecuting this suit shall be unsatisfactory to the said Hewitt or to the Cooper Hewitt Electric Company, in case the latter has an interest in such patent, he or it may employ an attorney to take part in the prosecution of the case

If any patent with reference to which royalty is payable hereunder is held to be invalid by any Court of final jurisdiction or by any inferior Court from whose decree no appeal is taken and prosecuted within the time prescribed by law, the Telephone Company shall thereafter be under no obligation to pay royalties with reference to such patent. If the patent is held to be valid but limited in scope, the Telephone Company shall thereafter be under no obligation to pay royalties under that patent, with reference to its utilization of the C. H. T. devices or method of operation held not to be covered by such patent.

8. Hewitt warrants that he has full right to grant the licenses and make the agreements herein set forth, and that he has not made and will not make any agreement in conflict herewith.

9. Hewitt agrees that he will, at any time or times on request of the Telephone Company, execute and deliver to the Telephone Company such further or other instruments as the latter may desire for fully vesting in it the license and rights herein conveyed.

10. It is agreed that the recognition of the validity of patents, arising out of the acceptance of this license, is limited to their validity in connection with C. H. T. devices as herein defined.

11. This agreement and license shall be binding upon and shall inure to the benefit of the parties hereto, and their several successors, legal representatives and assigns, except as otherwise specifically stated in this agreement. The Telephone Company's rights hereunder shall not be assignable or transferable except to an assignee or transferee who shall agree in all respects

to be bound by the obligations of the Telephone Company hereunder; and Hewitt agrees that he will cause any assignee or transferee of his rights hereunder or of his patents under which this license is granted, to be bound by all of his obligations as expressed herein.

IN WITNESS WHEREOF, Hewitt has executed this instrument and the Telephone Company has caused this instrument to be executed by its proper officers thereunto duly authorized, on the day and year first above written.

No. 781,001. Patented January 31, 1905.

UNITED STATES PATENT OFFICE.

PETER COOPER HEWITT, OF NEW YORK, N. Y., ASSIGNOR, BY MESNE ASSIGNMENTS, TO COOPER HEWITT ELECTRIC COMPANY, A CORPORATION OF NEW YORK.

MEANS FOR AMPLIFYING ELECTRICAL VARIATIONS.

SPECIFICATION forming part of Letters Patent No. 781,001, dated January 31, 1905.

Application filed May 16, 1902. Serial No. 107,004.

To all whom it may concern:

Be it known that I, PETER COOPER HEWITT, a citizen of the United States, and a resident of New York, in the county of New York and State of New York, have invented certain new and useful Improvements in Means for Amplifying Electrical Variations, of which the following is a specification.

In certain patents granted to me September 17, 1901, attention is called to the fact that the resistance of an inclosed vapor or gas carrying current in an electric circuit varies inversely with the current carried by the vapor. Accordingly if a varying potential be applied to an apparatus of the general character described in the patents referred to a variation of current will take place in the inclosed gas or vapor, and this variation of current will affect the entire circuit in which the apparatus is included, and if the circuit is so arranged that the gas or vapor apparatus shall represent a considerable portion of the total resistance of the circuit the variations of current thus caused in the conducting gas or vapor will cause comparatively large variations in the entire circuit.

It is customary to operate electric circuits for various purposes by causing variations of potential in the circuit, such variations being utilized to influence appropriate receiving apparatus. In the present invention I avail myself of the peculiar features of electrical resistance in a gas or vapor conductor to vary or magnify the effects produced by potential variations in a circuit. By virtue of the described characteristics of gas or vapor conductors it is possible, for instance, to translate variations of potential in a circuit into variations of current or quantity, and inasmuch as the conducting gas or vapor responds practically instantaneously to the applied variations of potential, currents of any practical rapidity or frequency can be made to undergo the described transformation and produce their effects upon a suitable receiving apparatus. As the practical result of an increase of applied potential is an increased flow of current, the original electrical impulses in the circuit may produce magnified effects as compared with those which the same impulses would produce if applied directly to the receivers.

The drawing herewith is a diagram of a typical circuit embodying my invention.

In the drawing, 1 is a suitable source of current supplying a circuit 2. Included in the circuit are a transmitting or potential-changing apparatus 3 and a receiving apparatus 4. The transmitting apparatus may be a telegraph-relay, a telephone-transmitter, or any other device adapted to vary the potential of the current in the circuit 2. The receiving apparatus 4 may be any suitable receiver adapted to respond to variations of current in the line.

A circuit made up as described is common enough in the electrical arts. The improvement forming the subject of the present application consists in causing the described circuit to be affected by the peculiar action of an inclosed gas or vapor apparatus, (shown at 5.) This apparatus may be such an apparatus as described in my patents above referred to as a "gas" or "vapor" electric lamp, or it may be an apparatus generally similar to such a lamp, but having no light-giving quality by reason of being specially adapted to the purposes of this invention without regard to the matter of light. For this purpose the device may be made with a comparatively short gas or vapor path and having such cross-section that with the current normally traversing it the vapor or gas may become but faintly luminous. The resistance of the circuit outside the device 5 is practically constant except for the slight variations introduced through the instrumentality of the potential-changing apparatus 3. As the resistance of the device 5 varies substantially inversely with the quantity of the current flowing, or, to put it another way, requires a definite voltage to pass a definite current therethrough, any diminution, for instance, of the potential applied to its terminals by reason of an increase of resistance on the part of the device 3 will result in not only the diminution of flow of current due to the increased resistance of the device 3, but also to an additional diminution due to the change brought about in the device 5 by the decreased current resulting from the decreased potential at the terminals of the device 5. Likewise an increase of potential at the terminals of the device 5, due to a change of resistance in the outside circuit, will cause an increase of current-flow therethrough greatly in excess of the change due to the change of resistance in the other portions of the circuit. In other words, the changes of resistance in other portions of the circuit than the device 5 bring about such variations of conditions in the device 5 as to augment the variations of current-flow through the entire circuit. It should be borne in mind, however, that the resistance of the other portions of the circuit than the device 5 serves in a measure as a balancing resistance for the device 5; otherwise a decrease of resistance in the external circuit might result in a continuing unchecked decrease of the total resistance of the circuit including the device 5. The device 5 itself, however, has in a measure a self-corrective tendency within certain limits, due to internal variations of resistance resulting from changes in its temperature. The temperature of the device 5 may be taken into consideration when measuring the device for ohmic resistance, as its ohmic resistance varies with the temperature which is brought about by variations in the flow of current and also by the surrounding conditions. The method of controlling these is set forth in the patents hereinbefore referred to. The variations in the amount of current through which the device 5 may be made to operate may be made quite wide by constructing it with the required heat-radiating capacity. It will now be understood that the receiving apparatus 4 will be affected by a comparatively large current and will respond with greater certainty and effectiveness than it otherwise would. The same amplification of the effects of potential changes in the circuit takes place whatever be the degree of potential increase or variation.

When the resistance of the element 5 is made a considerable portion of the total resistance of the circuit, the effect of the changes of resistance in the element named will be very marked, especially when the source of supply is great.

By reason of the gaseous condition of the conducting medium employed the gas or vapor apparatus responds instantly to potential changes in the current without essential loss of energy. In this respect it differs from other materials or substances, because in such other materials or substances work has to be done in the process of reducing the resistance whereby a loss of energy is caused and the time element becomes a considerable factor, while in my apparatus the amount of material so affected is so small that the energy required to produce the result may be practically neglected.

Means for starting the flow of current through the apparatus are set forth in the patents hereinbefore referred to.

I claim as my invention—

1. The combination in an electric circuit, of a source of potential variation, a receiving apparatus adapted to translate the variations caused by the source, and an inclosed gas or vapor conducting medium.

2. The combination in an electric circuit, of a source of potential variations, a receiver adapted to respond to changes of current in the circuit, and a quickly-responding inclosed gas or vapor conducting medium whose resistance decreases with increments of temperature.

UNITED STATES PATENT OFFICE.

PETER COOPER HEWITT, OF NEW YORK, N. Y., ASSIGNOR, BY MESNE ASSIGNMENTS, TO COOPER HEWITT ELECTRIC COMPANY, A CORPORATION OF NEW YORK.

METHOD OF AMPLIFYING ELECTRICAL VARIATIONS.

SPECIFICATION forming part of Letters Patent No. 781,002, dated January 31, 1905.

Application filed May 16, 1902. Serial No. 107,[illegible].

To all whom it may concern:

Be it known that I, PETER COOPER HEWITT, a citizen of the United States, and a resident of New York, in the county of New York and State of New York, have invented certain new and useful Improvements in Methods of Amplifying Electrical Variations, of which the following is a specification.

In certain patents granted to me September 17, 1901, notably in the patents numbered 682,695, 682,696, and 682,697, attention is called to the fact that the resistance of an inclosed vapor or gas carrying current in an electric circuit varies inversely with the current carried by the vapor. Accordingly if a varying potential be applied to an apparatus of the general character described in the patents referred to a variation of current will take place in the inclosed gas or vapor, and this variation of current will affect the entire circuit in which the apparatus is included, and if the circuit is so arranged that the gas or vapor apparatus shall represent a considerable portion of the total resistance of the circuit the variations of current thus caused in the conducting gas or vapor will cause comparatively large variations in the entire circuit.

It is customary to operate electric circuits for various purposes by causing variations of potential in the circuit, such variations being utilized to influence appropriate receiving apparatus. In the present invention I avail myself of the peculiar features of electrical resistance of a gas or vapor conductor to vary or magnify the effects produced by potential variations in a circuit.

By virtue of the described characteristics of gas or vapor conductors it is impossible, for instance, to translate variations of potential in a circuit into variations of current or quantity, and inasmuch as the conducting gas or vapor responds practically instantaneously to the applied variations of potential currents of any practical rapidity or frequency can be made to undergo the described transformation and produce their effects upon a suitable receiving apparatus. As the practical result of an increase of applied potential is an increased flow of current, the original electrical impulses in the circuit may produce magnified effects as compared with those which the same impulses would produce if applied directly to the receivers.

The drawing herewith is a diagram of a typical circuit embodying my invention.

In the drawing, 1 is a suitable source of current supplying a circuit 2. Included in the circuit are a transmitting or potential changing apparatus 3 and a receiving apparatus 4. The transmitting apparatus may be a telegraph-relay, a telephone-transmitter, or any other device adapted to vary the potential of the current in the circuit 2. The receiving apparatus 4 may be any suitable receiver adapted to respond to variations of current in the line.

A circuit made up as described is common enough in the electrical arts.

The improvement forming the subject of the present application consists in causing the described circuit to be affected by the peculiar action of an inclosed gas or vapor apparatus, (shown at 5.) This apparatus may be such an apparatus as described in my patents above referred to as a "gas" or "vapor" electric lamp, or it may be an apparatus generally similar to such a lamp, but having no light-giving quality by reason of being specially adapted to the purposes of this invention without regard to the matter of light. For this purpose the device may be made with a comparatively short gas or vapor path and having such cross-section that with the current normally traversing it the vapor or gas may become but faintly luminous. The resistance of the circuit outside the device 5 is practically constant except for the slight variations introduced through the instrumentality of the potential-changing apparatus 3. As the resistance of the device 5 varies substantially inversely with the quantity of the current flowing, or, to put it another way, requires a definite voltage to pass a definite current therethrough, any diminution, for instance, of the potential applied to its terminals by reason of an increase of resistance on the part of the device 5 will result in not only the diminution of flow of current due to the increased resistance of the device, but also to an additional diminution due to the change brought about in the device 5 by the decreased current resulting from the decreased potential at the terminals of the device 5. Likewise an increase of potential at the terminals of the device 5 due to a change of resistance in the outside circuit will cause an increase of current-flow therethrough greatly in excess of the change due to the change of resistance in the other portions of the circuit. In other words, the changes of resistance in other portions of the circuit than the device 5 bring about such variations of conditions in the device 5 as to augment the variations of current-flow through the entire circuit. It should be borne in mind, however, that the resistance of the other portions of the circuit than the device 5 serves in a measure as a balancing resistance for the device 5. Otherwise a decrease of resistance in the external circuit might result in a continuing unchecked decrease of the total resistance of the circuit including the device 5. The device 5 itself, however, has in a measure a self-corrective tendency within certain limits due to internal variations of resistance resulting from changes in its temperature. The temperature of the device 5 must be taken into consideration when measuring the device for ohmic resistance, as its ohmic resistance varies with the temperature which is brought about by variations in the flow of current and also by the surrounding conditions. The method of controlling these is set forth in the patents hereinbefore referred to. The variations in the amount of current through which the device 5 may be made to operate may be made quite wide by constructing it with the required heat-radiating capacity.

It will now be understood that the receiving apparatus 4 will be affected by a comparatively large current and will respond with greater certainty and effectiveness than it otherwise would.

The same amplification of the effects of potential changes in the circuit takes place whatever be the degree of potential increase or variation.

When the resistance of the element 5 is made a considerable portion of the total resistance of the circuit, the effect of the changes of resistance in the element named will be very marked, especially when the source of supply is great.

By reason of the gaseous condition of the conducting medium employed the gas or vapor apparatus responds instantly to potential changes in the current without essential loss of energy. In this respect it differs from other materials or substances, because in such other materials or substances work has to be done in the process of reducing the resistance, whereby a loss of energy is caused and the time element becomes a considerable factor, while in my apparatus the amount of material so affected is so small that the energy required to produce the result may be practically neglected.

Means for starting the flow of current through the apparatus are set forth in the patents hereinbefore referred to.

I claim as my invention—

1. The method of amplifying potential variations caused in an electric circuit, which consists in applying the said variations to a quickly-responding medium in the circuit, thereby causing a change in current-flow through such medium, and by such change of current-flow producing in such medium a change of specific resistance resulting in a still further change in current-flow through the circuit.

2. The method of amplifying energy variations caused in an electric circuit of which an inclosed gas or vapor forms part, and of translating the effects of such amplified variations, which consists in affecting the conducting gas or vapor by variations of current, transforming such variations of current into variations of resistance, and applying such currents to a suitable translating device.

3. The method of amplifying energy variations caused in an electric circuit including an inclosed conducting gas or vapor and electrodes therefor, which consists in affecting the conducting gas or vapor by variations of current, and thereby transforming such variations into corresponding amplified variations of current.

No. 749,791. Patented January 19, 1904.

UNITED STATES PATENT OFFICE.

PETER COOPER HEWITT, OF NEW YORK, N. Y., ASSIGNOR, BY MESNE ASSIGNMENTS, TO COOPER HEWITT ELECTRIC COMPANY, A CORPORATION OF NEW YORK.

MEANS FOR REPRODUCING ELECTRICAL VARIATIONS.

SPECIFICATION forming part of Letters Patent No. 749,791, dated January 19, 1904.

Application filed May 16, 1902. Serial No. 107,601. (No model.)

To all whom it may concern:

Be it known that I, Peter Cooper Hewitt, a citizen of the United States, and a resident of New York, in the county of New York and State of New York, have invented certain new and useful Improvements in Means for Reproducing Electrical Variations, of which the following is a specification.

In certain Letters Patent of the United States—for instance, those issued to me on the 17th day of September, 1901—I have shown and described gas or vapor electric lamps in which the resistance of the lamp can be kept practically constant by a suitable construction of the lamps. I have found that the resistance of these lamps is subject to control by other means than those set forth in the patents referred to and that the lamps may be used as a very sensitive means for varying the resistance of an electric circuit. For example, the resistance of these lamps is readily affected by a magnetic field in proximity to it and the variations in the field may be made to reproduce themselves as a varying electrical resistance in the lamp. The same effect is produced by a magnet or solenoid upon an apparatus of this general character whether the apparatus is designed to operate as a lamp or light-giving medium or is especially designed as a means of varying the current in a circuit. In other words, in applying the described apparatus to the purposes of this invention I may so construct it as to make it capable of giving light, or I may prefer to inclose an appropriate gas or vapor in a container so proportioned as to accomplish the special results aimed at by this invention irrespective of whether the apparatus is then designed to produce light or not.

In order to produce the desired variations of resistance in the gas or vapor apparatus, I generally locate the magnet or solenoid at the side of the apparatus where it will distort the current passing between the positive and the negative electrodes, it being found that the active current in an apparatus of this sort tends to be deflected by a magnetic field. The stronger the magnet the higher the electrical resistance of the apparatus.

The present invention relates to means for applying this characteristic of my lamp or vapor apparatus to the purpose of reproducing the variations of current in an electric circuit whether a wholly independent circuit or a branch of a divided circuit. Such applications of the apparatus are useful for a variety of purposes, the action being a conversion of varying magnetic intensities due to varying current affecting a magnetic field into variations of electrical resistance which may be made to affect a circuit in which my vapor apparatus is included.

In the accompanying drawings, Figure 1 is a diagram illustrating an organization of circuits for carrying out my invention, and Figs. 2 and 3 illustrate modifications.

Referring to Fig. 1, 1 represents a source of electric currents of any desired character connected in the circuit 3, which is provided with any suitable means 4 for varying the magnetic effects in a magnet 5. The magnet 5 is so placed with reference to a chamber 6, containing a conducting gas or vapor, which in turn is connected in a circuit 7, provided with any suitable source 8 of electric currents. The variations in the flow of current through the circuit 7 may be caused to act upon a receiving device 9 of any desired character. The means for varying the magnetic effects in the magnet 5 may, for example, be a telephone-transmitter, and the receiving device 9 may be a telephone-receiver. The gas or vapor within the tube or container is of any appropriate character, as more fully set forth in my patents hereinbefore referred to, and the negative electrode 10 may be of mercury or of any other suitable means for receiving the current from the gas or vapor and likewise the positive electrode 11, although for convenience I have in the drawings indicated it as being of a solid material held within the chamber 6.

The location of the magnet 5 and its particular relation to the chamber 6 may be variously modified. In Fig. 1 I have represented the magnet with its core in a plane parallel with the chamber 6. In Fig. 2 it is illustrated as having one pole directed in a plane perpendicular to the chamber 6, and in Fig. 3 I have shown the core as being prolonged, so as to partially or wholly embrace the chamber, thereby tending to direct the lines of force transversely through the gas or vapor; but the constructions and positions of the magnet may be variously modified, the object being to cause the lines of force to pass into the vapor-path.

It is possible by means of my invention to produce in the secondary or receiving circuit electrical variations of greater magnitude than the original electrical variations of the primary or transmitting circuit. This is due to the fact that a given magnetic variation may cause a wider fluctuation of effective resistance in the gas or vapor than the fluctuations of electrical energy producing the variation of the magnetic field of force. Accordingly by employing one of my lamps or vapor apparatuses, as described, I may magnify the vibrations of the circuit not by inductive effects, but by varying the ohmic resistance of the circuit in which the apparatus is included.

I have mentioned a telephone-circuit merely for purposes of illustration. The amplifications due to changes in resistance of my apparatus may be applied to other circuits as well, including circuits carrying currents of large quantity.

It will further be understood that the applications of my invention are not limited to cases where it is desired to amplify the primary variations, but are useful also where it is merely desired to reproduce them in the same or even less magnitude.

Means for starting the flow of current through the apparatus are set forth in the patents hereinbefore referred to.

I claim as my invention—

1. As a means for reproducing the variations of current in an electric circuit, an electromagnet subject to the influence of said variations, and a gas or vapor apparatus of the character described located in the field of force of the said magnet.

2. As a means for reproducing current variations in an electric circuit, an electromagnet subject to the influence of said variations, a gas or vapor apparatus located in the field of force of the said magnet, and a receiving apparatus in circuit with the gas or vapor apparatus.

3. The combination of a telephonic transmitting-circuit, a telephone-receiver, a circuit including the latter, and an inclosed gas or vapor path included in the latter circuit, and an electromagnet traversed by electric currents due to the effects of the transmitting-circuit, and acting upon the gas or vapor path, substantially as described.

4. The combination with a telephonic transmitting-circuit, an electromagnet included therein, a telephonic receiving-circuit having an inclosed gas or vapor path inserted therein, the gas or vapor path and the electromagnet occupying such relative positions that a portion at least of the lines of force from the electromagnet act upon the gas or vapor path.

UNITED STATES PATENT OFFICE.

PETER COOPER HEWITT, OF NEW YORK, N. Y., ASSIGNOR, BY MESNE ASSIGNMENTS, TO COOPER HEWITT ELECTRIC COMPANY, A CORPORATION OF NEW YORK.

METHOD OF REPRODUCING ELECTRICAL VARIATIONS.

SPECIFICATION forming part of Letters Patent No. 749,792, dated January 19, 1904.

Application filed May 16, 1902. Serial No. 107,602. (No model.)

To all whom it may concern:

Be it known that I, PETER COOPER HEWITT, a citizen of the United States, and a resident of New York, in the county of New York and State of New York, have invented certain new and useful Improvements in Methods of Reproducing Electrical Variations, of which the following is a specification.

In certain Letters Patent of the United States—for instance, those issued to me on the 17th day of September, 1901—I have shown and described gas or vapor electric lamps in which the resistance of the lamp can be kept practically constant by a suitable construction of the lamps. I have found that the resistance of these lamps is subject to control by other means than those set forth in the patents referred to and that the lamps may be used as a very sensitive means for varying the resistance of an electric circuit. For example, the resistance of these lamps is readily affected by a magnetic field in proximity to it, and the variations in the field may be made to reproduce themselves as a varying electrical resistance in the lamp. The same effect is produced by a magnet or solenoid upon an apparatus of this general character whether the apparatus is designed to operate as a lamp or light-giving medium or is especially designed as a means of varying the current in a circuit. In other words, in applying the described apparatus to the purposes of this invention I may so construct it as to make it capable of giving light, or I may prefer to inclose an appropriate gas or vapor in a container so proportioned as to accomplish the special results aimed at by this invention irrespective of whether the apparatus is then designed to produce light or not. In order to produce the desired variations of resistance in the gas or vapor apparatus, I generally locate the magnet or solenoid at the side of the apparatus, where it will distort the current passing between the positive and the negative electrodes, it being found that the active current in an apparatus of this sort tends to be deflected by a magnetic field. The stronger the magnet the higher the electrical resistance of the apparatus. The present invention relates to means for applying this characteristic of my lamp or vapor apparatus to the purpose of reproducing the variations of current in an electric circuit whether a wholly independent circuit or a branch of a divided circuit. Such applications of the apparatus are useful for a variety of purposes, the action being a conversion of varying magnetic intensities, due to varying current affecting a magnetic field into variations of electrical resistance which may be made to affect a circuit in which my vapor apparatus is included.

In the accompanying drawings, Figure 1 is a diagram illustrating an organization of circuits for carrying out my invention, and Figs. 2 and 3 illustrate modifications.

Referring to Fig. 1, 1 represents a source of electric currents of any desired character connected in the circuit 3, which is provided with any suitable means 4 for varying the magnetic effects in a magnet 5. The magnet 5 is so placed with reference to a chamber 6, containing a conducting gas or vapor, which in turn is connected in a circuit 7, provided with any suitable source 8 of electric currents. The variations in the flow of current through the circuit 7 may be caused to act upon a receiving device 9 of any desired character. The means for varying the magnetic effects in the magnet 5 may, for example, be a telephone-transmitter, and the receiving device 9 may be a telephone-receiver. The gas or vapor within the tube or container is of any appropriate character, as more fully set forth in my patents hereinbefore referred to, and the negative electrode 10 may be of mercury or of any other suitable means for receiving the current from the gas or vapor and likewise the positive electrode 11, although for convenience I have in the drawings indicated it as being of a solid material held within the chamber 6. The location of the magnet 5 and its particular relation to the chamber 6 may be variously modified. In Fig. 1 I have represented the magnet with its core in a plane parallel with the chamber 6. In Fig. 2 it is illustrated as having one pole directed in a plane perpendicular to the chamber 6, and in Fig. 8 I have shown the core as being prolonged, so as to partially or wholly embrace the chamber, thereby tending to direct the lines of force transversely through the gas or vapor; but the constructions and positions of the magnet may be variously modified, the object being to cause the lines of force to pass into the vapor-path.

It is possible by means of my invention to produce in the secondary or receiving circuit electrical variations of greater magnitude than the original electrical variations of the primary or transmitting circuit. This is due to the fact that a given magnetic variation may cause a wider fluctuation of effective resistance in the gas or vapor than the fluctuations of electrical energy producing the variation of the magnetic field of force. Accordingly by employing one of my lamps or vapor apparatuses as described I may magnify the vibrations of the circuit not by inductive effects but by varying the ohmic resistance of the circuit in which the apparatus is included.

I have mentioned a telephone-circuit merely for purposes of illustration. The amplifications due to changes in resistance of my apparatus may be applied to other circuits as well, including circuits carrying currents of large quantity. It will further be understood that the application of my invention is not limited to cases where it is desired to amplify the primary variations, but is useful also where it is merely desired to reproduce them in the same or even less magnitude.

Means for starting the flow of current through the apparatus are set forth in the patents hereinbefore referred to.

I claim as my invention—

1. The method of reproducing current variations in an electrical circuit, which consists in transforming these variations into a varying field of force, causing the said field of force to act magnetically upon an inclosed gas or vapor so as to produce variations of electrical resistance in another circuit.

2. The method of producing in a circuit containing an inclosed conducting gas or vapor, variations of electrical resistance corresponding to variations of current in another circuit, which consists in causing the variations of current in the second-named circuit to act magnetically upon the said gas or vapor and thereby vary the electrical resistance thereof and of the circuit.

3. The method of reproducing in a translating device included in a circuit containing an inclosed gas or vapor path, effects corresponding to electrical variations in another circuit, which consists in converting said electrical variations into magnetic variations, and causing such magnetic variations to act upon an inclosed gas or vapor path, thereby producing variations in the current-flow of the first-named circuit.

4. The method of reproducing in a translating device included in a circuit containing an inclosed gas or vapor, effects corresponding to variations of electrical resistance in another circuit, which consists in causing in the last-named circuit variations of current adapted to affect the translating device, converting these variations of current into magnetic variations, and causing such magnetic variations to act upon the inclosed gas or vapor.

No. 749,793. Patented January 19, 1904.

UNITED STATES PATENT OFFICE.

PETER COOPER HEWITT, OF NEW YORK, N. Y., ASSIGNOR, BY MESNE ASSIGNMENTS, TO COOPER HEWITT ELECTRIC COMPANY, A CORPORATION OF NEW YORK.

REGULATOR FOR GAS OR VAPOR ELECTRIC APPARATUS.

SPECIFICATION forming part of Letters Patent No. 749,793, dated January 19, 1904.

Application filed May 16, 1902. Serial No. 107,603. (No model.)

To all whom it may concern:

Be it known that I, PETER COOPER HEWITT, a citizen of the United States, and a resident of New York, in the county of New York and State of New York, have invented certain new and useful Improvements in Regulators for Gas or Vapor Electric Apparatus, of which the following is a specification.

The appearance of what I have called the "negative" flame in certain types of gas or vapor electric lamps has been referred to in an application for Letters Patent of the United States, Serial No. 99,333, filed by me on the 21st day of March, 1902. In the said application reference is made to the fact that under ordinary conditions the negative flame acts as a resistance to the passage of the electric current, particularly when the flame stands in the direct line of the current between the positive and negative electrodes of the lamp. The application referred to describes mechanical means for removing the negative flame from the direct path of the current, and thereby lessening the total lamp resistance. In the same application attention is called to the fact that when the negative flame is acted upon by a magnet or solenoid the condition of lowest lamp resistance is attained when the flame lies in the direct path of the current through the lamp. It is found, in other words, that either a permanent or an electro magnet will so influence the negative flame as to change its character as a resisting medium and cause it to actually lessen the normal lamp resistance. In this connection it is to be noted that the tendency of the flame is to project itself or lie along the lines of magnetic force, and in this way the flame is made very steady by the action of a magnet, so that the normal resistance of a lamp in which the negative flame is mechanically controlled can be governed without any essential fluctuation. Accordingly if it be desired to construct a lamp with as low a normal resistance as possible, assuming a vertical type of lamp in which the negative electrode is at the bottom of the transparent container, the proper position for the magnet or solenoid would be directly below the negative electrode, with the lines of force projecting toward the lamp-electrode. This would cause a projection of the flame in an upward direction, thus bringing it into a right line with the current between the electrodes, thereby minimizing the normal lamp resistance. On the other hand, it may sometimes be desired to operate lamps at a resistance higher than the lowest possible resistance, in which case the magnet or solenoid may be located in such relation to the negative electrode as to throw the flame into other than a vertical position, thus predetermining the lamp resistance at a desired value within certain limits.

When a magnetic field is utilized for fixing the position of the negative flame or for deflecting it from the direct line between the electrodes, a permanent magnet may be employed, if desired, or an electromagnet supplied from any suitable source. By using an electromagnet, however, and putting it in series with the lamp and then so placing it with respect to the negative electrode as to deflect the flame away from the direct line it is possible to secure excellent regulation of the lamp resistance in a manner which will be described in the specification which follows. It should be said that the length of the flame and under certain conditions the amount of the deflection depend upon the strength of the magnet employed. When, for example, a vertical magnet is placed so that its poles are located anywhere below the negative electrode in a vertical lamp, successive increases of magnetic strength will project the flame farther and farther, but in a fixed direction, while if the magnetic pull be located above the surface of the negative electrode successive increases of magnetic strength will project the flame farther and farther away from the vertical, thereby increasing the lamp resistance. By these means variations in the circuit of the electromagnet, if an independent circuit, may be recreated in the circuit of the lamp with varying intensity, depending on the magnetic circuit and on the lamp-circuit.

My invention is illustrated in the accompanying drawings, in which—

Figure 1 is an elevation of one of my vertical lamps in which the flame is projected vertically upward by an electromagnet underneath the lamp. Fig. 2 is a similar view of a vertical lamp in which the flame is projected at an angle, and Fig. 3 is a diagram illustrating electromagnetic means for automatically regulating the resistance of a lamp.

In Fig. 1 the main lamp-tube is shown at 1, the respective positive and negative electrodes at 2 and 5, the same being severally connected with leading-in wires 7 and 8. Below the negative electrode 5 is arranged an electromagnet 10, energized by a suitable source 11. Under the conditions illustrated in this figure the negative flame 12 is projected vertically upward, thus giving to the lamp its lowest resistance.

In Fig. 2 the relations are changed only to the extent that the magnet 10 is shifted a little to one side, thereby causing the flame to be projected at an angle to the vertical, under which conditions the lamp has an increased resistance as compared with the lamp shown in Fig. 1.

In Fig. 3 the magnet 10 is arranged at the side of the lamp and somewhat above the surface of the negative electrode 5. Here the flame 12 is deflected, as shown, the deflection being still more marked in case the strength of the magnet 10 increases. The magnet is here arranged in series with the lamp, so that any change of potential on the line will be felt not only in the lamp but also in the magnet 10. For example, should the conditions of the circuit be so altered as to cause too great a flow of current the strength of the magnet 10 will be increased, the flame 12 will be deflected, so as to increase the lamp resistance, in consequence of which the excessive flow of current is checked. Thus the arrangement illustrated in Fig. 3 is adapted to cause a very sensitive regulation of the lamp-circuit. When the electromagnet is in an independent circuit, variations in the magnet-circuit will be reproduced in the lamp-circuit, and this arrangement may be used for many purposes—for instance, as a relay.

Means for starting the flow of current through the apparatus are set forth in certain patents issued to me on the 17th day of September, 1901.

The results described above are more readily accomplished when the flame is proceeding from a projecting point, as shown at 13 in Fig. 1, or is fixed by a plate floating on the mercury, the plate having a hole in its center, as illustrated at 14 in Fig. 2.

It is manifest that the operation of the device forming the subject of the present invention is the same whether the apparatus is used as a lamp or a source of light or for any other purpose.

I claim as my invention—

1. In an electric vapor apparatus in which a path is provided for the electric current between a positive and a negative electrode, and in whose normal operation a negative flame is developed at the negative electrode, magnetic means for projecting the flame in such a direction with relation to the path of the current between the electrodes as to produce a definite normal resistance in the apparatus.

2. In an electric circuit, an electric vapor apparatus and an electromagnet in series therewith, the magnet being placed at the side of the apparatus and in operative proximity thereto.

3. The combination with an electric circuit containing a gas or vapor apparatus, of an electromagnet, placed in such relation to the negative electrode of the apparatus that electrical variations in the magnet-circuit will be reproduced in the circuit of the apparatus.

UNITED STATES PATENT OFFICE.

PETER COOPER HEWITT, OF NEW YORK, N. Y., ASSIGNOR TO COOPER HEWITT ELECTRIC COMPANY, A CORPORATION OF NEW YORK.

ELECTRODE FOR VAPOR ELECTRIC APPARATUS.

SPECIFICATION forming part of Letters Patent No. 758,650, dated May 3, 1904.

Application filed January 13, 1904. Serial No. 188,838. (No model.)

To all whom it may concern:

Be it known that I, PETER COOPER HEWITT, a citizen of the United States, and a resident of New York, county of New York, State of New York, have invented certain new and useful Improvements in Electrodes for Vapor Electric Apparatus, of which the following is a specification.

In the operation of a vapor electric device where the "negative electrode resistance" is comparatively small this resistance is apt to be irregular. The current enters the negative electrode at a spot and has the tendency to be constantly wandering over its surface, being visible as a bright wandering spot or flame. I have found that this may be overcome under the same conditions and that the resistance may be made stable. I have also discovered that physical or chemical disintegration takes place at the point where the current enters the negative electrode and that by constructing the electrode so that physical or chemical change will take place at a predetermined spot more easily than another the current can be made to enter this spot and cease wandering over the surface of the negative electrode. In the case where the negative electrode consists of a volatilizable material this may be done by extending from it a point of metal or other material. This point when it becomes heated by the current will cause vaporization of the material forming the electrode on or at its surface of contact and consequent fixing of the entering of the current at that place. If this point be of such a material as becomes wetted by the material of the negative electrode, it then will act somewhat in the same manner as a wick and its operation appears certain and stable. The disintegration of the negative electrode at a particular spot may be brought about by chemical means and also by the physical character and shape of the electrode.

In the accompanying drawing I have shown one form of vapor device illustrating the invention.

Referring to the drawing, 1 represents an inclosing chamber, in the present instance in the form of a tube having an enlargement 2 at one end. This enlargement serves as a condensing and cooling chamber for the vapor of the negative electrode, which for convenience in this instance will be referred to as "mercury." The negative electrode is here shown as located at the end of the tube remote from the condensing-chamber 2, which has the negative electrode 3. The positive electrode 4 is represented within the condensing-chamber. Suitable leading-in conductors 5 and 6 are connected with the respective electrodes 3 and 4. The leading-in conductor 5 is here shown as being provided with an extension of platinum, as 7, projecting slightly above the surface of the negative electrode. This extension may be comparatively thin and, in fact, may be virtually a wire. When mercury is used as the negative electrode, platinum serves excellently as the material from which to form the point 7.

The particular device here shown is represented in the form especially suited for electric illuminating purposes; but the same principle applies when the device is used for transformers or other purposes.

I claim as my invention—

1. In an electric vapor device of the character described, a fluid electrode, and a point of solid conducting material projecting above the surface thereof.

2. In an apparatus of the class described, an electrode of mercury having a solid conducting material projecting above the surface thereof.

3. In an apparatus of the class described, an electrode of mercury having a body of platinum projecting above the surface thereof.

4. In a gas or vapor electric device having a liquid negative electrode, steadying means at the negative electrode comprising a solid wetted material in contact therewith, the general surface of the solid being in a different plane from the general surface of the liquid.

Signed at New York, in the county of New York and State of New York, this 6th day of January, A. D. 1904.

PETER COOPER HEWITT, OF NEW YORK, N. Y., ASSIGNOR, BY MESNE ASSIGNMENTS, TO COOPER HEWITT ELECTRIC COMPANY, A CORPORATION OF NEW YORK.

MEANS FOR SUPPRESSING THE RESISTANCE OF THE NEGATIVE-ELECTRODE FLAME IN ELECTRIC VAPOR APPARATUS.

954,434. Specification of Letters Patent. **Patented Apr. 12, 1910.**

Application filed March 21, 1902. Serial No. 99,333.

To all whom it may concern:

Be it known that I, PETER COOPER HEWITT, a citizen of the United States, and a resident of New York, in the county of New York and State of New York, have invented certain new and useful Improvements in Means for Suppressing the Resistance of the Negative-Electrode Flame in Electric Vapor Apparatus, of which the following is a specification.

This invention relates to improvements in the class of vapor apparatus described and shown in various patents issued to me on the 17th day of September and the 3rd day of December, 1901.

The operation of electric vapor lamps, such for instance, as that type of the Cooper-Hewitt lamp in which mercury is used as the negative electrode, is generally accompanied by the appearance at the negative electrode of a flame which, while being somewhat unstable when the surface of the negative electrode is irregular or subject to alteration, proceeds from the negative electrode in a direction at right angles to the surface at which the current enters the said electrode. By a proper selection of the plane of the negative electrode surface, the direction which this negative flame shall take, can, accordingly, be predetermined. The investigation of the resistance of a vapor lamp, such as described, shows that when this negative flame takes the direction of the path of the current between the positive and negative electrodes of the lamp, the total resistance of the lamp is considerably greater than when the negative flame puts off at an angle to the current path. The excess in resistance under the conditions first named, may equal or exceed fifteen per cent. of the total resistance. It will be understood that the negative flame referred to is practically useless as a source of light, for which reason the electromotive-force required to overcome the resistance occasioned by this flame serves no useful function in the lamp and is not only practically wasted but is detrimental. In order to insure that the energy applied to a lamp of this class shall be utilized in the light-giving portion thereof, without needless waste, I provide means whereby the surface of the negative electrode shall be so arranged as to insure the projection of the negative flame outside the path of current through the lamp.

The present invention relates to means for accomplishing that end.

It is also found that the direction of the negative flame is changed by the action of a magnet or solenoid, the flame tending to lie in and along the lines of force. Where it is desired that the negative flame should be out of a right line to the main path of the current, a magnet or a solenoid may furnish a convenient means for accomplishing this result but the deflection of the flame in this way by a magnet or solenoid has the effect of increasing the resistance of the lamp instead of decreasing it. In general it may be said that a wide deflection of the negative flame is desirable when produced by mechanical means, and a condition of no deflection is desirable when produced by magnetic means. The effect of the magnetic action is to maintain the flame in a stable condition.

The provisions referred to in the foregoing paragraphs are based upon the fact that the negative flame proceeds substantially at right angles to the entrance plane of the current. This means that the entrance surface of the negative electrode should be out of a plane at right angles to the path of the current, in order to cause a suitable position of the negative flame.

I have illustrated my invention in the accompanying drawings, in which—

Figure 1 is a longitudinal section of a mercury vapor lamp showing the negative flame in line with the path of current between the electrodes; Fig. 2 is a similar view of a lamp so constructed as to cause the negative flame to put off at an angle to the current path; Fig. 3 is a section of the lower part of one of my lamps, illustrating a particular form of negative electrode; and Fig. 4 is a longitudinal section of a lamp similar to that shown in Fig. 1, combined with a deflecting electro-magnet.

In the drawings, 1 is a tube or container of glass and 2 and 5 are, respectively, the positive and negative electrodes of my lamp. The electrodes are connected through the walls of the lamp to the respective lead-wires, 7 and 8. In Figs. 1, 2 and 3, the positive electrode is of iron and the negative electrode is of mercury, or mercury in combination with a projecting piece of metal, generally iron. In Fig. 1, the negative electrode is of pure mercury. The negative flame is shown at, 3, projecting at right angles from the upper surface of the mercury in the direction of the path of the current between the electrode 2 and the electrode 5. In practice, it is found that the surface of the mercury electrode is subject to more or less distortion at the point where the current enters the electrode, for which reason the surface at that point may not be in a plane at right angles to the main path of the current, so that the negative flame, when the negative electrode consists entirely of mercury, may not always take the direction indicated in Fig. 1. But inasmuch as the negative flame may take the direction indicated in Fig. 1, it is desirable that this should be guarded against, by providing an entering surface for the current which shall always lie in a direction other than a right angle from the path of the current. I have found that, while the current appears to enter the negative electrode at a small point on its surface, yet it prefers to enter at a point upon a plane surface rather than at an edge or actual mechanical point or summit. A suitable formation of the negative electrode is illustrated in Fig. 2 wherein a piece of iron, 6, projects up through the mercury 5 and has perpendicular surfaces at which the current enters. With this construction the negative flame is thrown off nearly or quite at right angles to the path of the current between the electrodes.

Fig. 3 illustrates a modification of the negative electrode, in which a piece, 6, of iron, projects above the mercury and is provided with a conical or pyramidal shape, the current entering the iron at an angle other than a right angle to the main path of the current, thus causing a deflection of the negative flame.

As a simple mode of illustrating the deflection of the flame by means of magnetic force, I have shown in Fig. 4, a magnet, 12, outside the enlargement in which the negative electrode surface lies. The effect of the magnet is to deflect or turn the negative flame approximately as indicated in the drawing. The magnet may be a permanent magnet or an electro-magnet supplied from a separate source or in a series or shunt relation to the lamp. In another application, Serial Number 107,608, filed May 16, 1902, and issued as a patent on January 19, 1904, Number 749,793, I have shown and described this feature in greater detail and have claimed it as a regulating device. Also in a divisional application Serial Number 123,873, filed September 18, 1902, claims are made upon the horizontal lamp described herein.

It is manifest that this invention would apply equally well to a gas or vapor electric lamp and to a gas or vapor electric apparatus designed for any other use.

In another application Serial Number 548,071, filed March 11, 1910, which is a division of this application, I have made claims involving certain features shown and described herein.

I claim as my invention:

1. In a vapor electric apparatus, a container of suitable shape and dimensions, a positive and a negative electrode therein, and means for causing the surface of the negative electrode at which the current enters it to lie in a plane at an oblique angle to the path of the current between the two electrodes whereby the flame is caused to project itself out of the path of the current.

2. In a vapor electric apparatus, a suitable container, a positive and a negative electrode within the same, an enlargement surrounding the exposed surface of the negative electrode, and means for so shaping the surface of the negative electrode as to cause it to present an entering plane for the current traversing the lamp, which plane lies at an oblique angle to the direct path of the current between the electrodes.

3. In a gas or vapor apparatus of the character described, a container, a positive electrode, a liquid negative electrode, and a solid electrode extension projecting above the surface of the negative electrode, the surface of the projection forming an oblique angle with reference to the surface of the liquid negative electrode.

UNITED STATES PATENT OFFICE.

PETER COOPER HEWITT, OF NEW YORK, N. Y., ASSIGNOR TO COOPER HEWITT ELECTRIC COMPANY, OF NEW YORK, N. Y., A CORPORATION OF NEW YORK.

MEANS FOR REPRODUCING ELECTRICAL VARIATIONS.

991,304. Specification of Letters Patent. Patented May 2, 1911.

Application filed July 7, 1904. Serial No. 215,377.

To all whom it may concern:

Be it known that I, PETER COOPER HEWITT, a citizen of the United States, and resident of New York, county of New York, State of New York, have invented certain new and useful Improvements in Means for Reproducing Electrical Variations, of which the following is a specification.

The present invention relates to improvements upon the devices disclosed in Letters Patent of the United States Numbers 749,791 and 749,792, issued to me on the 19th day of January, 1904. In the earlier of the patents mentioned I describe means for reproducing variations of current in an electric circuit, such means consisting of an electro-magnet subject to the influence of said variations and a gas or vapor apparatus located in the field of force of the said magnet. In the present invention I make use of similar means, but with modifications which involve novel methods of operation and novel arrangment of apparatus.

In operating vapor electric apparatus of the general character described in my prior patents, it is found that a "bur" is produced at the positive electrode. This may appear in a visible form, as luminous radiations from the positive electrode or it may be incapable of being appreciated by the sense of sight. The appearance at the positive electrode may be described as a protuberance and the appearance of a protuberance is accompanied by a variation in the resistance at the positive electrode, which we may speak of as a protuberance resistance at the said electrode. The protuberance may be single or it may be a plurality of protuberances lying with an appearance of symmetry on the positive electrode under certain conditions. The protuberance acts as an interference to the positive current and this interference may be modified by means of a magnet, the material of the positive electrode, or by means of a particular construction of the surroundings of the positive electrode, so as to create variations of period in the current through the apparatus. By a proper proportioning of the various forces at work, the variations may be made very long, or may be superimposed on each other, or they may be variations so rapid as to be inaudible. The arrangement as a whole may be utilized for creating different variations in the direct current in any circuit where such variations are necessary, for example, in multiplex telegraphy or kindred systems.

By the effects of variations produced upon the positive protuberance the operation of varying the field of force will produce a note commencing at the audible point and extending above that point to an indefinite region. Accordingly, if the field of force be varied by a microphone for example, the result should show a variation in its note corresponding to the variations of the microphone, whereby the apparatus may be caused to produce notes corresponding or inverse to the note of the microphone, whereby a telephone relay is provided, the correspondence or inversion, as the case may be, depending on whether the source of the magnetic field is a magnet whose force is varied by a coil, or whether the coil is a coil creating the magnetism itself. The current from the positive electrode gives a note which is constant and dependent on the conditions established. By means of a permanent magnet the point where the current passes from the positive electrode may be shifted so as to give a shriller note. By varying the connections so that the microphone is subject to the sound waves produced by a telephone instrument connected so as to give the note of the source, varying effects may be produced, the action being that the variations in the current from the microphone passing through the magnet coil influence the vapor path in various ways. A relation exists between the current and the magnetic force. The effects may be received by telephone receivers connected with primary and secondary coils as is illustrated in the accompanying drawings.

The invention will be better understood by referring to the accompanying diagrams, Figures 1 and 2, representing different embodiments of my invention.

Referring to the first figure of the drawing, 1 is a hermetically sealed vessel of glass or other suitable material containing a negative electrode 2, and positive electrodes, 3 and 4. The latter may be of some suitable material, such as iron, and the negative electrode may be of mercury or other conductor and preferably capable of low electrical resistance and having a point or equivalent projection from the surface. The electrode 4 is a supplemental electrode, the main electrodes being 2 and 3. The apparatus having been started, the negative electrode resistance may be maintained in a condition of being broken down by means of current flowing between the electrodes 4 and 2 and supplied through mains 5 and 6, connected with a source furnishing a supply of current in one direction. I may now place so as to influence the container 1, a magnet, 7, connected in circuit with a telephonic transmitter, 8, or other source of variation. In circuit with the main electrodes I may place a telephone receiver, or other receiver, 9, in shunt to a reactance coil, 10, which may be the primary of a transformer, the secondary of which is shown at 11 as being connected in a circuit with a second telephonic receiver, 12, in which case the first may be omitted, if desired. If, now, the transmitter 8 be affected by vibrations, say through the human voice, the variations of magnetic effect in the circuit including the magnet 7 will be reproduced in the vapor device 1 and consequently in the circuit connected with the main electrodes 3 and 2 of the said vapor device. Effects of the variations caused by the changes in the field of force of the magnet 7 being thus reproduced can be observed in the receiver 9 or the receiver 12, as the case may be. Inasmuch as a slight variation in the field of force of the magnet 7 may cause a considerable variation in the resistance of the vapor device, which last named variation will be reproduced in the receiving circuit, the apparatus as a whole may serve as a relay adapted to magnify the effects originally produced at the transmitter 8. In the circuit between the main electrodes 3 and 2 I include any suitable source of current, such, for example, as the battery, 13, indicated on the drawing, and further these effects may be amplified by including in the circuit a vapor device such as my lamps, care being taken to keep the negative electrode resistance in a state of good conductivity in which the resistance varies substantially inversely with the current, which forms a suitable proportion of the resistance of its circuit for augmenting the variations. The transmitter circuit also contains the usual battery, 14. In the circuit of the direct current source I may insert the resistance, as 15, and I may also insert the resistance, 16, in the circuit between the main electrodes. When placed in a similar manner as shown and described in Fig. 1 the magnet 7 will directly influence what I have called the protuberance resistance at the positive electrode. By thus influencing this resistance, the interference of the protuberance with the positive current is modified and thus variations of period in the current through the apparatus are produced. It will be understood that a different location of the magnet 7, as by placing it lower down along the container would still produce variations in the resistance of the apparatus, which variations would be reproduced in the external circuit. The effects produced by such a relation of the parts has already been made the subject of patents issued to me; namely, 749,791 and 749,792.

In Fig. 2 I show a different embodiment of my invention, the parts 2 and 4 and the circuit 5 serving substantially the same function as before. In the circuit described I show in this instance a direct current source, 17, serving to keep the apparatus alive. The main positive electrode in this embodiment of the invention appears at 18 as a ring of conducting material surrounding a reëntrant portion 19 of the tube or container 1. The ring 18 is supported upon lead-wires, 20 and 21, leading into the apparatus through tubular extensions, 22 and 23, respectively. Into the reëntrant portion of the device I insert the core, 24, of a magnet, 25, the core may be provided with pole-pieces, 26 and 27, formed, respectively on arms, 28 and 29, which are in one piece with the core, 24, instead of a plain straight core. The pole pieces are so arranged as to lie outside the tube or container 1 in proximity to the positive electrode 18. The coils of the magnet 25 are connected with the terminals of a microphone or telephonic transmitter, 30. As before, the positive electrode is connected with a battery or other source 13 with one side of a reactance device 10, the other side of which is connected with the negative electrode 2. The reactance device 10 is, in this instance as before, the primary of a transformer and in shunt to the said primary is a telephonic receiver 9 while the secondary 11 of the said transformer is connected with a telephonic receiver 12. From what has been said respecting the action of the apparatus illustrated in Fig. 1, the action of this apparatus will be clearly understood.

I claim as my invention:—

1. As a means for reproducing the variations of current in an electric circuit, an electromagnet subject to the influence of said variations, and a gas or vapor apparatus of the character described located in the field of force of the said magnet, the magnet being placed in such relation to the positive electrode as to cause the variation of the protuberance resistance to be large relative to any variation produced by the said magnet in the vapor column resistance.

2. As a means for reproducing the variations of current in an electric circuit, an electro-magnet subject to the influence of said variations, and a gas or vapor apparatus, of the character described located in the field of force of the said magnet, the

magnet being placed in proximity to the positive electrode, a main circuit through the gas or vapor apparatus, and supplemental means for keeping the said apparatus alive.

3. As a means for reproducing current variations in an electric circuit, an electromagnet subject to the influence of said variations, a gas or vapor apparatus located in the field of force of the said magnet, means for passing electric current through said apparatus, and a receiving apparatus subject to the influence of variations of resistance in the circuit of the gas or vapor apparatus, in combination with supplemental means for maintaining the gas or vapor apparatus alive.

4. The combination with a vapor device including a hermetically sealed and completely exhausted container and an anode, and vaporizable reconstructing cathode therein, the said anode and the protuberance therefrom being located in a relatively narrow extension of the main body of said container, of a magnet adapted to receive and transmit variations of energy placed adjacent to said protuberance and varying the resistance thereof in relation to the variation of its received energy.

5. The combination with a telephonic transmitting circuit, a telephone receiver, a circuit including the latter, a gas or vapor path, means for passing electric current therethrough, said path being so related to the latter as to affect the same by variations of resistance in the circuit of the gas or vapor apparatus, and an electro-magnet traversed by electric currents due to effects in the transmitting circuit, and acting upon the gas or vapor path, and supplemental means for maintaining the gas or vapor electric apparatus alive.

6. The combination with a vapor device including a hermetically sealed and completely exhausted container, an anode, a vaporizable reconstructing cathode and a surface extending upward from the main surface of said cathode therein, of a magnet adapted to receive and transmit variations of energy located adjacent to said protuberance and producing therein a change of resistance corresponding to variations in its received energy, said resistance changes being relatively great as compared to any variations in the resistance of the vapor column.

7. The combination with a hermetically sealed and completely exhausted container, a plurality of anodes and a vaporizable reconstructing cathode in said container, a solid in contact with the surface of said cathode, means for passing continuous current from one of the said anodes to said cathode and means for varying the resistance of a vapor path to another of said anodes by ether waves from an outside source of electrical variations, of a receiving circuit including a telephone and a source of electromotive force in circuit with said last named anode and said cathode.

8. The combination with a generator of energy variations in the ether, of a vapor electric device including a cathode and an anode, a source of current therefor and a receiving circuit sensitive to rapid variations of electrical energy, said circuit including a separate anode in said vapor electric device, together with means for causing said energy variations in the ether to produce variations in the vapor path to said separate anode.

9. The combination with a generator of energy variations in the ether, of a vapor electric device, including a cathode, an anode, and a relatively excessive condensing chamber, a suitable source of current therefor and a receiving circuit sensitive to rapid variations of electrical energy, said circuit including a separate anode in said vapor electric device, together with means for causing said electrical variations in the ether to produce variations in the vapor path to said separate anode.

10. In a system of electrical distribution the combination with a hermetically sealed exhausted container and a mercury cathode therein, of anodes therein, each anode being in a tubular extension of said container together with a separate source of current connected with each anode and the said cathode.

Signed at New York, in the county of New York, and State of New York, this 30th day of June A. D. 1904.

Pring & Parker Article, Philosophical Magazine, 1912, Vol. 23, pp. 192-200.

IONIZATION PRODUCED BY CARBON AT HIGH TEMPERATURES

XVI. *The Ionization produced by Carbon at High Temperatures. By* J. N. Pring, *D.Sc., and* A. Parker, *University of Manchester.*[*]

The escape of negative electricity from heated carbon was noticed by Edison[†] when making experiments with lamp filaments. This leak of current from a heated filament to an adjacent electrode which is at a positive potential relative to the filament can, in some cases, become of the same order as that conducted through the filament. Edison found that when these filaments have been used for some time the ionization effect diminishes, but increases again if the carbon is allowed to stand.

O. W. Richardson[‡] made systematic measurements of the ionization produced by carbon. Use was made of a carbon filament and a surrounding metal cylinder, and between these a potential difference varying from 30 to 300 volts was maintained, the heated carbon being made negative. The current produced by ionization was conducted across to the surrounding metal. By exhausting to very low pressures, from 0.1 to 0.001 mm. the influence of the ionization of the surrounding gas was supposed to be eliminated, and the currents produced were considered to be due to the liberation of corpuscles from the carbon.

It had previously been stated by M'Clelland[§] that the negative ionization from metals is independent of the pressure over a range from 0.04 to 0.004 mm. The ionization currents found by Richardson, and attributed to the liberation of corpuscles, ranged from 10^{-8} to

---

[§] Proc. Cambr. Phil. Soc. x. p. 241; xi. p. 299.

2 amps. per square cm. of carbon, according to the temperature. A formula which had been deduced to show the relation between ionization and temperature was found to be in good agreement with the experimental results. In this equation $I = A\theta^{1/2} e^{-\frac{b}{\theta}}$ where I denotes the ionization, A and b are constants, and θ is the absolute temperature. In the case of carbon, Richardson found that $A = 10^{34}$ and $b = 9.5 \times 10^4$. According to this formula, the ionization will increase at a rate which at 1500° is about equal to the 50th power of the temperature. As is well known, there are no means of precisely estimating the temperature of thin filaments.

F. Deininger[†] investigated the ionization from carbon and various metals alone, and in presence of lime, and concluded that Richardson's formula applied in every case up to 1450°. Thus $\log I - \frac{1}{2} \log \theta$ was plotted against $\frac{1}{\theta} 10^4$, and found to give a straight line. No mention is made of the pressure.

H. A. Wilson[‡] investigated the ionization from platinum and found that this varied very much with the previous treatment of the metal. Thus, by long continued heating, or else by previously submitting to the action of nitric acid, the ionization was largely diminished. He concluded that the ionization from platinum is independent of the pressure from 0.2 to 0.001 mm., but that a reduction to $\frac{1}{250,000}$ of the original ionization is produced by removing the last traces of occluded hydrogen. Wilson states that in some experiments carried out with carbon he confirmed the general results of Richardson.

The present work was undertaken with a view to examine the ionization from carbon at temperatures which were more accurately measured than in previous work, to extend these up to about 2000°, and, at the same time, to notice what influence is exerted by the pressure of the surrounding gas and the condition of the carbon. No attention seems to have been paid by previous workers to the chemical purity of the carbon.

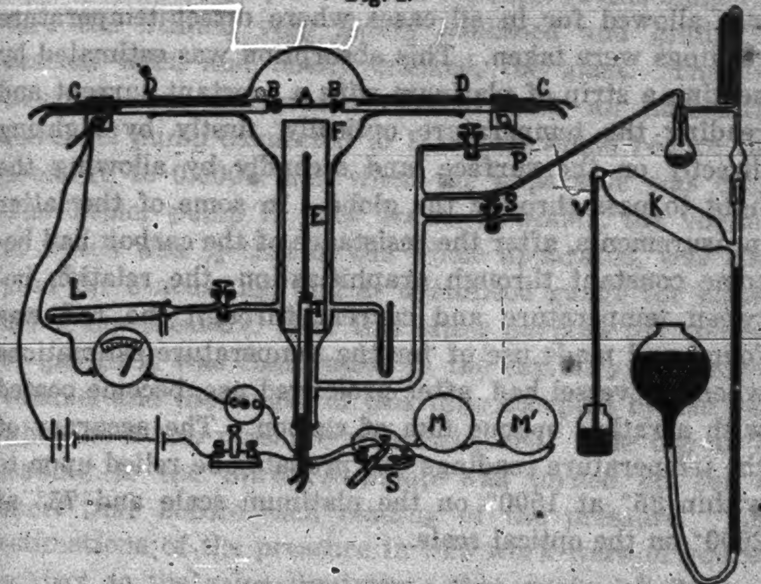
[‡] Phil. Trans. (1904) A. ccii. p. 243.

Fig. 1.



The apparatus used in the present work (fig. 1) was designed primarily for examining the phenomena at the anode during the discharge with high currents, and consisted of a tubular glass flask, in which a carbon rod (A) was supported by inserting in the graphite plugs B, B, which themselves were soldered into the water-cooled brass tubes C, C. An air-tight joint was made at D, D, by means of soft wax. The water-cooled tubes served for leading in the current which was used to heat the carbon. The carbon rod used was 5.1 cm. long and 0.50 mm. diameter, or 8.01 sq. cm. surface. This arrangement of the apparatus enabled the rod to be heated to 2200°.

Temperature Readings.—Accurate temperature readings were taken with a Wanner optical pyrometer. This was directly calibrated against a standardised thermocouple up to 1400°, and at the "black body" melting-point of platinum, 1545° *, and as carbon has been found to radiate approximately as a "black body," the temperature readings will follow closely the platinum scale. The small amount of absorption through the glass vessel was allowed for in all cases where direct temperature readings were taken. This absorption was estimated by heating a strip of platinum with a constant current and reading the temperature optically, firstly by sighting directly on the surface, and secondly by allowing the light to pass through the globe. In some of the latter measurements, after the resistance of the carbon had become constant through graphitization, the relation between temperature and current through the rod was found and made use of for the temperature estimations when the vessel had, after prolonged use, become coated with a rather opaque film of carbon. The accuracy of the temperature readings can probably be relied upon to within 35° at 1500° on the platinum scale and 75° at 2000° on the optical scale..

---

* Holborn and Henning, *Sitzungsber. k. Acad. Wiss. Berlin* (1905) xii. p. 311.

For the anode, a graphite rod (E) was soldered into the water-cooled brass tube (T), the top being placed at 4.8 cm. distance from the carbon (A). During the experiment, a large difference of potential (usually 330 volts) was maintained between E and A; the high-potential circuit being connected through the galvanometers M and M′ which were of different ranges, one giving a deflexion of one scale-division for 4.1×10^{-9} amp. and the other of one division for 6×10^{-7} amp. For higher currents these were replaced by a milliammeter reading to 0.5 amp. and for measuring currents during discharge an ammeter reading to 30 amps. was used. By means of the two-way switch S the galvanometers were thrown out of circuit except during the moment when readings were being taken.

Exhaustion of Apparatus.—In the early experiments use was made of lithium for reducing the pressure. For this purpose the metal was placed in an iron boat contained in a tube of Jena glass (L). By surrounding this tube by an electrical furnace, and using a thermo-junction pyrometer, it was found that beginning with low pressures absorption of the gas to within one per cent. of the volume took place at 450°, though at this temperature the lithium very slowly sublimed and gradually reacted with, and finally cracked, the glass. The exhaustion was afterwards effected with an automatic Sprengel pump connected to P, which would reduce the pressure to 0.0001 mm. when the apparatus was cold. The Töpler pump K (not drawn to scale), the volume of which was ⅙ that of the whole apparatus, was also used for evacuating, and as a McLeod gauge for measuring the pressure. For this latter purpose the volume of gas in K was compressed in the capillary, of known volume, and the length of this tube occupied by the gas when at 5 cm. pressure was measured. The tap at P leading to the Sprengel pump was turned off for a short time before each reading of the pressure. The estimations of the pressure in this work were of course subject to the same limitations that apply in all cases where use is made of the McLeod gauge, through the presence of condensible gases and surface condensation on glass.

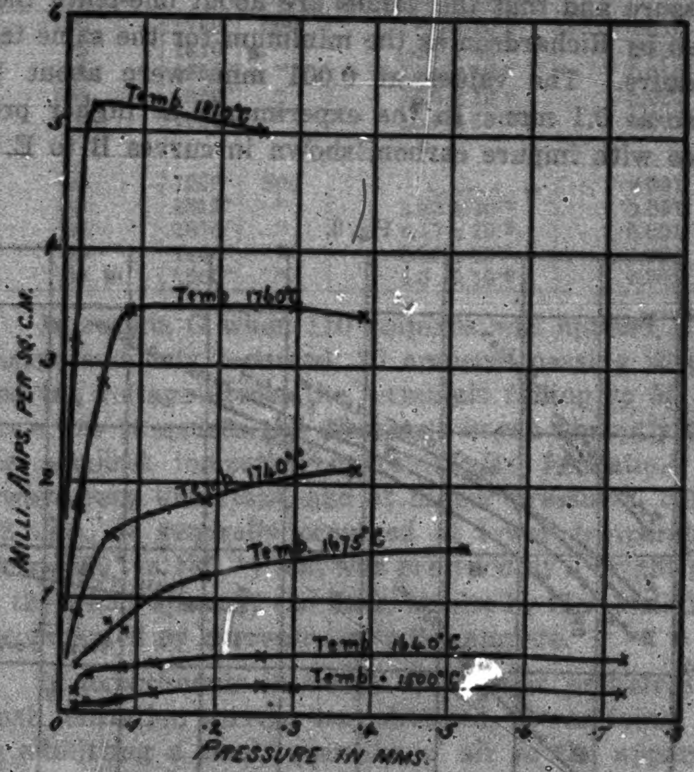
Purification of Carbon.—The carbon used consisted of amorphous retort carbon and contained about 2.5 per cent. ash (oxides of iron, silicon, &c.), and 0.2 per cent. of combined hydrogen. The method of purification employed consisted in heating for long intervals at temperatures varying from 1700° to 2000°, and maintaining very low pressures. In this way impurities are gradually volatilized away and occluded gases expelled. It has never been found possible to purify carbon completely *, on account of the tenacity with which it holds many elements in large quantities at temperatures greatly above their points of volatilization. (After use in the experiments below, the carbon was analysed by combustion in oxygen and found to contain 0.091 per cent. of ash.) The graphite rod E was occasionally heated during the above treatment by causing a discharge to pass between

* *Cf.* Pring, Trans. Chem. Soc. (1910). xcvii. p. 504.

this and the heated carbon rod. Suitable conditions of temperature of the rod and pressure were arranged, and a potential difference of about 250 to 350 volts was applied between the carbon and the graphite. When the discharge was once started, a voltage of 40 to 60 was sufficient to maintain a current of 20 to 30 amperes, and the graphite was gradually raised to a bright white heat at the end, and the inside glass cylinder (F) to the softening point. After heating the carbon rod in this manner for some 20 to 30 hours it was found possible, at any time when the apparatus was cold, to reduce the pressure in the vessel to 0.0001 mm. within 2 hours. On raising the temperature of the rod, however, the pressure always rose immediately and amounted to about 0.01 mm. when at 1800°. This could not be reduced any further by long continued heating and exhausting. After the globe had become coated with a thin film of carbon, the pressures obtained when the rod was heated were higher than before, and for a given temperature of the rod remained constant, even after heating and pumping for several days. This residual gas is probably due either to carbon monoxide which would be formed by reaction between the oxides of the glass and the deposited film of carbon, a reaction which would proceed to a certain equilibrium value at any given temperature, or else it is due to oxygen resulting from slight dissociation of the oxides in the glass, though the temperature of the latter, of course, never reached the softening point.

Measurement of Ionization.—A potential difference of about 330 volts was applied between E and A (fig. 1) except where otherwise stated, and the latter made negative. In this way it was hoped to collect most of the ions coming from the carbon. At this voltage, however, the original ionization must have been increased by collision, as only about half the current was obtained on using 200 volts. It was found that by placing the graphite rod E at 11 cm. instead of 4.8 cm. from the carbon, a fall in the ionization current of not more than one-fifth was caused. The results obtained when using impure carbon are shown in the form of curves in fig. 2,

Fig. 2.



where the ordinates denote the ionization current in milliamperes per 1 sq. cm. surface of carbon and the abscissæ, the pressures. In fig. 3 are seen the results of another series of experiments which were extended to much lower pressures, and where a higher degree of purity of the carbon was obtained. In this diagram the ordinates denote the logarithm of the ionization currents (in amperes) for one square cm. of cathode surface, and the abscissæ, the temperatures. The results obtained by Richardson are shown in this diagram at A. In the present work it was found that the minimum of ionization is not obtained at the pressures used by Richardson, but that the values fall continuously with diminution of pressure and with continued use of the same carbon as it becomes progressively purer. Beginning with higher pressures and unpurified carbon, it was found that the maximum ionization current is obtained at about 0.1 mm. pressure and that the values are about one-tenth those given by Richardson as the minimum for the same temperature. The values at 0.001 mm. were about 1/60 those at 0.1 mm. In the experiments at higher pressures with impure carbon, shown in curves B to E, at temperatures between 1250° and 1820°, if the values of log I — ½ log θ are plotted against $\frac{1}{\theta}\,10^4$, a straight line is obtained; but at higher temperatures, which were taken up to 2050°, and lower pressures, the ionization increased with the temperature far less than is required by Richardson's formula, and varied very much with the condition of the carbon. Curves B to E were carried out with impure carbon, and G and H after heating at temperatures between 1500° and 2100° and pressure between 0.005 and 0.05 mm. for a total period of about 40 hours. The values obtained in G and H, as typical experiments, are given in the table below.

In results G when 110 amperes was applied, a discharge suddenly occurred, 20 amperes passing through and the voltage across the terminals falling to 50. At these low pressures the discharge began abruptly from the smallest ionization current. Its formation was always very uncertain, and at higher pressures, 0.05 to 0.2 mm., it generally occurred at lower temperatures (*i. e.* 1550° to 1850°) and was preceded by a bright glow in the whole space of the flask, or else by blue striations, accompanied by currents up to 0.5 ampere.

In experiments in which at the low pressures the small ionization current was obtained, it was found that on admitting a small quantity of air to the apparatus the current immediately rose to values similar to those shown in curves B to E. There was no measurable positive ionization produced from the carbon, up to 2000°, when the field (of 200 volts) was reversed.

Summary.

Measurements were made of the ionization produced by heated carbon at definitely known temperatures between 1300° and 2050°, and at various pressures.

The negative ionization from heated carbon was found to fall continuously both with reduction of the pressure and with progressive purification of the carbon.

The lowest value found at 1300°, with a potential difference of 330 volts, was 1.5×10^{-9} ampere per square cm. surface of carbon, whereas Richardson found at this temperature 1.3×10^{-4}. At 2000° with a potential difference of 200 volts, the lowest value found was 4×10^{-7} ampere, while Richardson's formula gives, at this temperature, about 100,000 amperes.

Above 1800° the ionization only increased very slightly with the temperature.

These results clearly show that the large currents hitherto obtained with heated carbon cannot be ascribed to the emission of electrons from carbon itself, but that they are probably due to some reaction at high temperatures between the carbon or contained impurities and the surrounding gases which involves the emission of electrons.

We are deeply indebted to Prof. Rutherford and Dr. H. Geiger for much valuable advice during the course of this work.

Physical Laboratories,
Victoria University,
Manchester.

Addendum.

Effects similar to the above results obtained with carbon have been noticed by Soddy [*] in the case of the Wehnelt lime cathode. It was found that, at very low pressures, this cathode ceased to produce ions, whereas, according to previous experimenters, greater saturation currents were given the lower the pressure. Soddy concludes that electronic emission can only account for a negligible fraction of the total current, the remainder being carried by the residual gas.

Richardson [†] reaffirms the opinion that the negative leak from hot platinum is independent of the pressure at low pressures, and that these gases "only appear to increase the fundamental electronic discharge from the hot cathode by a process involving the occurrence of ionization by collisions."

Wehnelt [‡] also contradicts the above inference of Soddy, and states that in the best possible vacuum the total current is sustained by the electrons emitted from the glowing oxides, and indeed at all pressures below about 0.1 mm.

Inventor.
John Ambrose Fleming
By his Attorneys

UNITED STATES PATENT OFFICE.

JOHN AMBROSE FLEMING, OF LONDON, ENGLAND, ASSIGNOR TO MARCONI WIRELESS TELEGRAPH COMPANY OF AMERICA, OF NEW YORK, N. Y., A CORPORATION OF NEW JERSEY.

INSTRUMENT FOR DETECTING ELECTRIC OSCILLATIONS.

954,619. Specification of Letters Patent. Patented Apr. 12, 1910.

Application filed January 2, 1908. Serial No. 409,484.

To all whom it may concern:

Be it known that I, John Ambrose Fleming, doctor of science, a subject of the King of Great Britain, residing at University College, Gower Street, in the county of London, England, have invented new and useful Improvements in Instruments for Detecting Electric Oscillations, of which the following is a specification.

My invention has reference to that type of electrical oscillation detector described by me in the United States patent specification No. 803684 dated 7th November 1905.

In this specification I described an oscillation detector subsequently called an oscillation valve or glow lamp detector, which consists of an electric glow lamp of the ordinary type, but having within the glass bulb a metal plate or cylinder carried on an insulated terminal sealed through the glass. When the filament is rendered incandescent by an electric current, it emits negative ions or corpuscles or electrons and these ionize the residual gas in the bulb, and give to the space a unilateral conductivity by which negative electricity can pass from the hot filament to the cold insulated plate or cylinder within the bulb, but not in the opposite direction. I employed this device as an electric wave detector in radiotelegraphy by connecting the insulated plate or cylinder to one terminal of an oscillation transformer inserted in the receiving circuit of the radiotelegraphic apparatus, and the other terminal of this oscillation transformer was connected through a galvanometer or telephone to the negative terminal of the filament.

I have discovered after many experiments that tungsten in various forms and particularly in a form in which it is employed as the filament in a glow lamp is highly efficient for this purpose since the amount of negative electricity emitted at the highest possible working temperature may be from ten to twenty times as great as that emitted by carbon in an ordinary carbon filament. I am unable to explain the reason of this superiority; it is not merely that a tungsten filament can be raised to a higher temperature than a carbon filament, for metals such as tantalum which are closely analogous to tungsten and which can be raised to an equally high temperature are not much superior to carbon at any temperature at which they can be worked in practice. I have also discovered that a cylinder of carbon acts better as the cold conductor in the bulb than the metallic cylinders heretofore employed. I construct such a metallic or semi-metallic filament glow lamp with a tubular glass bulb and a cylinder of carbon sealed into the bulb, surrounding but not touching the filament, and connected to a platinum wire sealed through the glass. Furthermore, I employ this glow lamp as an oscillation detector as follows:—The filament is rendered incandescent by an insulated battery having in series with it a rheostat or variable resistance for controlling the current. Across the terminals of this battery I place another high resistance having a sliding contact in it, so as to make contact with any desired point on this resistance.

In using this detector in wireless telegraphy the receiving circuit must comprise a closed circuit having inductance and containing a condenser. If the telegraphy is conducted by electric waves it is necessary also to connect an antenna either directly or indirectly with this condenser circuit. I then connect the insulated cylinder included within the bulb of the lamp with one plate of the condenser in the oscillation circuit, and I connect the other plate of this condenser with the sliding contact on the resistance across the glow lamp battery terminals. In this circuit I also include a telephone or current detecting instrument. A current then flows from the battery through the filament rendering it incandescent, and also in virtue of the emission of negative electricity from the filament a current flows from it through the vacuous space to the metal cylinder and through the telephone or other current detector. The conductivity of this vacuous space or ionized rarefied gas is a function of the electromotive force acting to drive the current through it. I find that if the position of the sliding contact on the resistance across the terminals of the battery is so adjusted that corresponding thereto the conductivity curve of the ionized gas has a very sudden change in curvature, the superposition of an oscillatory potential difference between the filament and cylinder upon the steady potential difference causes very sudden changes in the current strength through the telephone and therefore an emission of sound provided that the steady potential difference is of the necessary critical value. The arrangement described is therefore a very sensitive detector of oscillations in the condenser circuit to which the glow lamp is attached and therefore can serve as an electric wave detector in inductive or radiotelegraphy, since the sound in the telephone or indication of the equivalent current detector can be controlled from the transmitting end and cut up into Morse or other signals as required, to transmit by electric waves or magneto electric induction intelligence to a distance.

In the drawing accompanying and forming a part of this specification, I have illustrated one embodiment of my invention. Referring to this drawing it will be seen that in carrying my invention into effect I employ a tubular form of glass bulb *a* which may be an inch or more in diameter and five or six inches in length. In this I insert a cylinder *b* of carbon which is sprung into the glass tube so as to fit the walls tightly. This cylinder has a platinum wire *c* twisted or welded to it which is sealed through the glass, so as to make an external electrical connection. The bulb *a* should have a good vacuum such as is usually employed with lamps having metallic filaments. The metallic filament *d* is formed of tungsten in the form used as a filament in ordinary glow lamps and is connected to conductors *e* carried on a glass tubular stem *f* sealed into the bulb. The filament *d* should be of such a length that it is entirely covered by the metal cylinder *b*. It is convenient to have the filament of such length and thickness that the voltage required to bring it to incandescence at which its duration may not be less than several hundred hours, is of the order of 18 volts or so.

In applying this glow lamp as a detector in radiotelegraphy I arrange it as follows:— A battery *g* of secondary cells is provided which may conveniently be a dozen or more cells, and wires *h* are brought from the terminals of this battery to the terminals *e* of the filament of the lamp, a variable resistance *j k* being inserted in the circuit. It is convenient to divide this resistance into two, one namely *j* of from say 0 to 120 ohms being for coarse adjustment and the other *k* of from say 0 to 5 ohms being for fine adjustment. By means of these resistances the current of the lamp may be adjusted to have any required value. A voltmeter *l* should also be placed across the terminals of the filament to regulate the voltage. In addition I place across the terminals of the battery *g* a high resistance *m* of the potentiometer type, that is to say, a resistance which may be two or three hundred ohms or more, the terminals of which are connected to the terminals *h* of the battery. A double high resistance telephone *n* (the resistance of each telephone being at least five or six hundred ohms) has one terminal connected to a slider *o* which can make contact with any required point on the resistance *m* and the other terminal connected to one plate of a condenser *p*. The other plate of the condenser *p* is connected with the metal cylinder of the lamp. The condenser *p* is inserted in a circuit possessing inductance, which is directly or inductively connected with a receiving antenna. As shown the circuit connecting the two plates of the condenser *p* contains an adjustable inductance *q* and the secondary of the jigger *r* the primary of which is in the aerial *s*. When electric waves fall upon the receiving antenna they excite oscillations in the condenser circuit and oscillations are thus imposed upon the telephone circuit connecting the metal cylinder or plate in the lamp with the sliding contact and high resistance connected across the terminals of the battery or other source of continuous electric current.

In operating the arrangement, the first step is to bring the filament to a high incandescence at which it would be working approximately at one watt per candle and at which it will have such a temperature, approximately 2800° C., that it will diffuse into the vacuous space negative ions discharged from the incandescent filament. The filament having been rendered incandescent to this temperature, the observer applies the telephone to his ear and if electric wave trains are falling upon the receiving antenna *s*, it will be found that on moving the slider *o* along the potentiometer resistance *m* from one end to the other, there is a certain point at which sounds will be heard in the telephone better than at any other point. The exact position of the slider *o* must be determined by trial for it varies with every valve owing to slight differences in the vacuum and temperature of the filament. The detector above described is suitable as the receiver in radiotelephony, as well as for signals on the Morse or other alphabetic code.

What I claim is:—

1. A rectifier or valve for electric oscillations, having one electrode composed of tungsten.

2. A rectifier or valve for electric oscillations, having one electrode composed of tungsten and one element composed of carbon.

3. A rectifier or valve for electric oscillations, comprising a metallic filament constituting one electrode, means for heating said filament, and a plate of carbon constituting another electrode thereof.

4. A rectifier or valve for electric oscillations, comprising a metallic filament consti-

tuting one electrode, means for heating said filament, and a curved plate of carbon circumferentially situated in relation to the longitudinal axis of said filament.

5. An oscillation valve in which the hot conductor is a filament of tungsten.

6. An oscillation valve comprising a heated electrode in combination with a cold electrode consisting of a mass of carbon.

7. An oscillation valve comprising a heated electrode in combination with a cold electrode consisting of a cylinder of carbon.

8. An oscillation valve in which the hot conductor is a filament of tungsten and the cold conductor is a cylinder of carbon.

9. The combination of an oscillation valve, a source of electricity heating the filament of the valve, a resistance across the terminals of the source, a circuit connected at one end to the cold conductor of the valve and at the other to an adjustable point of the resistance, means for producing oscillations and means for detecting an electric current in the circuit.

10. In combination with an oscillation valve, a source of electric current for energizing the filament thereof, an oscillatory circuit having one terminal connected with one element of said oscillation valve, the other terminal of said oscillatory circuit being adjustably connected with a resistance which is connected with opposite terminals of another element of said valve, and a translating device operatively connected with said circuits for indicating the presence of electric oscillations.

Inventor:

Lee de Forest

by Geo. K. Woodworth Atty

UNITED STATES PATENT OFFICE.

LEE DE FOREST, OF NEW YORK, N. Y., ASSIGNOR, BY MESNE ASSIGNMENTS, TO DE FOREST RADIO TELEPHONE CO., A CORPORATION OF NEW YORK.

SPACE TELEGRAPHY.

No. 879,532. Specification of Letters Patent. Patented Feb. 18, 1908.

Application filed January 29, 1907. Serial No. 354,662.

To all whom it may concern:

Be it known that I, LEE DE FOREST, a citizen of the United States, and a resident of New York, in the county of New York and State of New York, have invented a new and useful Improvement in Space Telegraphy, of which the following is a specification.

My invention relates to wireless telegraph receivers or oscillation detectors of a type heretofore described in my prior Letters Patent Nos. 824,637, June 26, 1906 and 836,070, November 13, 1906.

The objects of my invention are to increase the sensitiveness of oscillation detectors comprising in their construction a gaseous medium by means of the structural features and circuit arrangements which are hereinafter more fully described.

My invention will be described with reference to the drawings which accompany and form a part of the present specification, although it is to be understood that many modifications may be made in the apparatus and systems herein described without departing from the principles of my invention.

In the drawings, Figure 1 represents in diagram a wireless telegraph receiving system comprising an oscillation detecter constructed and connected in accordance with the present invention and Fig. 2 represents a space telegraph receiving system having a modified form of oscillation detector connected therein in a manner which constitutes one of the subjects matter of said invention.

V I_1 E is an elevated conductor system including the elevated conductor V, earth connection E, and primary I_1 of the transformer I, the secondary I_2 of which forms part of the tuned receiving circuit I_2 C. It will be understood of course that the aforesaid tuned receiving circuit may be associated with the elevated conductor system in any suitable manner.

D represents an evacuated vessel, preferably of glass, having sealed therein three conducting members, F, *a* and *b*, in Fig. 1 and F, *a'* and *b* in Fig. 2. The conducting member or electrode F is shown as consisting of a filament, preferably of metal, which is connected in series with the battery A or other source of electrical current of sufficient strength to heat said filament, preferably to incandescence. The conducting member *b*, which may be a plate of platinum, has one end brought out to the terminal 3. Interposed between the members F and *b* is a grid-shaped member *a*, which may be formed of platinum wire, and which has one end brought out to the terminal 1. The local receiving circuit, which includes the battery B, or other suitable source of electromotive force, and the signal indicating device T, which may be a telephone receiver, has its terminals connected to the plate *b* and filament F at the points 3 and 4 respectively. The means for conveying the oscillations to be detected to the oscillation-detector, are the conductors which connect the filament F and grid *a* to the tuned receiving circuit and, as shown, said conductors pass from the terminals 2 and 1 to the armatures of the condenser C.

I have determined experimentally that the presence of the conducting member *a*, which as before stated may be grid-shaped, increases the sensitiveness of the oscillation detector and, inasmuch as the explanation of this phenomenon is exceedingly complex and at best would be merely tentative, I do not deem it necessary herein to enter into a detailed statement of what I believe to be the probable explanation.

In associating an oscillation detector of the above mentioned type, said detector being now commonly known as the audion, with a closed tuned circuit, it will be noted by reference to Fig. 2, that the secondary I_2 closes a circuit containing a battery shown at B through the electrode *b*, conducting member *a'* and the conducting gaseous medium intervening between said electrode and member. Also by reference to Fig. 1, it will be seen that a similar closed circuit exists between said battery, and the electrode *b* and conducting member *a*. In order to close each of said circuits to the passage of direct current from the aforesaid battery therethrough, or to prevent the development of a difference of potential between the members *a* and *b*, or between *a'* and *b*, or to prevent the members *a* or *a'* from receiving an electrical charge from said battery, I insert the condenser C' in said otherwise mechanically closed circuit and find that the presence of said condenser produces a great increase in the sensitiveness of the oscillation detector as determined by the very marked increase in the sound produced in the telephone T when said condenser is present over the sounds produced therein under the same conditions when said condenser is not employed.

It will be understood that the circuit arrangements herein described with reference to the particular forms of audion herein disclosed may with advantage also be employed with various other types of audion.

I claim.

1. An oscillation detector comprising an evacuated vessel, an electrode inclosed therein, means for heating said electrode, a second electrode inclosed within said vessel, a local circuit having its terminals electrically connected to said electrodes, a conducting member inclosed within said vessel and located between said electrodes, and means for conveying the oscillations to be detected to the first mentioned electrode and said conducting member.

2. An oscillation detector comprising an evacuated vessel, two electrodes inclosed within said vessel, means for heating one of said electrodes, and a conducting member inclosed within said vessel and interposed between said electrodes.

3. An oscillation detector comprising an evacuated vessel, two electrodes inclosed within said vessel, means for heating one of said electrodes, and a grid-shaped member of conducting material inclosed within said vessel and interposed between said electrodes.

4. An oscillation detector comprising an evacuated vessel, a filament sealed therein, a source of electrical energy connected in series with said filament, an electrode sealed in said vessel, a local circuit having its terminals connected to said filament and electrode, respectively, said local circuit including a source of electromotive force and a signal indicating device, a grid of conducting material sealed in said vessel and interposed between said filament and electrode, and means for conveying the oscillations to be detected to said filament and grid.

5. An oscillation detector comprising an evacuated vessel, an electrode inclosed therein, means for heating said electrode, a second electrode inclosed within said vessel, a local circuit having its terminals connected to said electrodes, a conducting member inclosed within said vessel and located between said electrodes, a closed circuit for conveying the oscillations to be detected to said first mentioned electrode and conducting member, and a condenser in said closed circuit.

6. An oscillation detector comprising an evacuated vessel, two electrodes inclosed therein, means for heating one of said electrodes, a conducting member inclosed within said vessel and interposed between said electrodes, means for establishing a difference of electrical potential between said electrodes and means for preventing said conducting member from becoming electrically charged.

7. An oscillation detector comprising an evacuated vessel inclosing a sensitive conducting gaseous medium, three conducting members inclosed therein, a closed oscillation circuit, a circuit connecting an element of said oscillation circuit with two of said members, a condenser in said circuit, a signal-indicating device, and a circuit connecting said device with one of said two members and with the third member.

8. An oscillation detector comprising an evacuated vessel, two electrodes inclosed therein, means for heating one of said electrodes, a conducting member inclosed within said vessel and interposed between said electrodes, means for establishing a difference of electrical potential between said electrodes and means for preventing the establishment of a difference of electrical potential between one of said electrodes and said conducting member.

9. An oscillation detector comprising an evacuated vessel, two electrodes inclosed therein, means for heating one of said electrodes, a grid of conducting material inclosed within said vessel and interposed between said electrodes, means for establishing a difference of electrical potential between said electrodes and means for preventing said grid from becoming electrically charged.

10. An oscillation detector comprising an evacuated vessel, two electrodes inclosed therein, means for heating one of said electrodes, a grid of conducting material inclosed within said vessel and interposed between said electrodes, means for establishing a difference of electrical potential between said electrodes and means for preventing the establishment of a difference of electrical potential between one of said electrodes and said grid.

11. An oscillation detector comprising an evacuated vessel, an electrode inclosed therein, means for heating said electrode, a second electrode inclosed within said vessel, a local circuit having its terminals electrically connected to said electrodes, a grid of conducting material inclosed within said vessel and located between said electrodes, and means for conveying the oscillations to be detected to the heated electrode and grid.

12. An oscillation detector comprising an evacuated vessel, an electrode inclosed therein, means for heating said electrode, a second electrode inclosed within said vessel, a local circuit having its terminals connected to said electrodes, a grid of conducting material inclosed within said vessel and located between said electrodes, a closed circuit for conveying the oscillations to be detected to the heated electrode and grid, and a condenser in said closed circuit.

13. An oscillation detector comprising an

evacuated vessel, an electrode inclosed therein, means for heating said electrode, a second electrode inclosed within said vessel, a local circuit having its terminals electrically connected to said electrodes, said local circuit including a source of electromotive force and a signal indicating device, a grid of conducting material inclosed within said vessel and located between said electrodes, and means for conveying the oscillations to be detected to the heated electrode and grid.

14. An oscillation detector comprising an evacuated vessel, two electrodes, one of which is a filament, inclosed within said vessel, means for heating said filament, and a conducting member inclosed within said vessel and interposed between said electrodes.

15. An oscillation detector comprising an evacuated vessel, two electrodes inclosed within said vessel, means for heating one of said electrodes, a grid of conducting material inclosed within said vessel and interposed between said electrodes, a local circuit connecting said electrodes, and a source of electromotive force and signal indicating device in said local circuit.

16. An oscillation detector comprising an evacuated vessel, two electrodes, one of which is a filament, inclosed within said vessel, means for heating said filament, and a grid of conducting material inclosed within said vessel and interposed between said electrodes.

17. An oscillation detector comprising an evacuated vessel, two electrodes inclosed within said vessel, means for heating one of said electrodes, a conducting member inclosed within said vessel and interposed between said electrodes, and a local circuit including a source of electromotive force connecting said electrodes.

18. An oscillation detector comprising an evacuated vessel, two electrodes inclosed within said vessel, means for heating one of said electrodes, a grid of conducting material inclosed within said vessel and interposed between said electrodes, a local circuit including a source of electromotive force connecting said electrodes and a signal indicating device associated with said local circuit.

19. An oscillation detector comprising an evacuated vessel, two electrodes, one of which is a filament, inclosed within said vessel, means for heating said filament, a grid of conducting material inclosed within said vessel and interposed between said electrodes and a local circuit including a source of electromotive force connecting said electrodes.

20. An oscillation detector comprising an evacuated vessel, two electrodes inclosed therein, means for heating one of said electrodes, a conducting member inclosed within said vessel, a closed oscillation circuit, a circuit connecting one element of said oscillation circuit with one of said electrodes and said conducting member, and a condenser in said circuit.

21. An oscillation detector comprising an evacuated vessel, two electrodes inclosed therein, means for heating one of said electrodes, a conducting member inclosed within said vessel, a closed oscillation circuit, a circuit connecting one element of said oscillation circuit with one of said electrodes and said conducting member, a condenser in said circuit, a signal indicating device and a circuit connecting said device with the other of said electrodes and said conducting member.

In testimony whereof, I have hereunto subscribed my name this 21st day of Dec. 1906.

LEE DE FOREST.

PLAINTIFF'S EXHIBIT No. 214.

Modification
OF
License Agreement
Dated July 1, 1920

GENERAL ELECTRIC COMPANY

AND

AMERICAN TELEPHONE AND TELEGRAPH COMPANY

July 1, 1926

AGREEMENT dated July 1, 1926, between General Electric Company, a New York corporation (herein called the General Company), and American Telephone and Telegraph Company, a New York corporation (herein called the Telephone Company).

Whereas, the parties hereto heretofore entered into an agreement made the first day of July, 1920, granting certain reciprocal licenses primarily in respect of electrical apparatus, but because at said date the art in certain of the fields dealt with in said agreement had not progressed to a point at which it was possible fully to comprehend the problems involved, disputes have arisen between the parties as to the meaning of various provisions of said agreement; and

Whereas, certain provisions of said agreement are not, as a practical matter, workable in the present state of the art; and

Whereas, unless said disputes are settled and said agreement made workable in practice progress in the fields dealt with in said agreement will be greatly hampered and delayed, and the parties desire to modify said agreement for the purpose of settling said disputes and making said agreement workable in practice;

Now, in consideration of the premises and the mutual agreements herein contained, the parties agree each with the other as follows:

I. Said agreement made the first day of July, 1920, shall be and is modified to read as follows:

Agreement made the first day of July, 1920, between General Electric Company, a New York corporation (herein called the General Company), and American Telephone and Telegraph Company, a New York corporation (herein called the Telephone Company).

Whereas, the General Company is engaged in the manufacture and sale in the United States of apparatus and systems for the generation, distribution and utilization of electricity for light, heat, power, traction and associated purposes, and in the manufacture and sale of a general line of electrical and power apparatus, and, directly and through subsidiaries, is engaged in the purchase of apparatus of various kinds from others and in the sale thereof; and is also engaged in the manufacture and sale of wireless apparatus; and

WHEREAS, the Telephone Company and the Companies of the Bell System and their subsidiaries are engaged in the operation of telephone and telegraph systems and in the manufacture, purchase and sale of telephone and telegraph and other electrical apparatus; and

WHEREAS, each party is in possession of information, patents and inventions applicable to, and has research organizations engaged in investigations bearing upon, not only its own business but also the business of the other party; and

WHEREAS, various patents or applications for patents of the parties are involved in interference with each other in the United States Patent Office; and

WHEREAS, the restrictions upon each party imposed by the patent rights of the other and the uncertainties arising out of interferences have tended to, and if permitted to continue, will hamper and delay, progress in the development and production of wire and wireless telephone and telegraph and phonograph apparatus and systems; and

WHEREAS, the effective and prompt development of the arts in question can be secured only by the free and frank co-operation and exchange of information between the parties, which can not well take place if improvements and knowledge resulting from one party's co-operation with the other party may without its consent be made available in its field to the use of others;

Now, in consideration of the premises and the mutual agreements herein contained, it is agreed as follows:

ARTICLE I.

DEFINITIONS.

For the purposes of this agreement the following terms are defined as follows:

"*Wire telephony*" is the art of communicating or reproducing sound waves (created, directly or indirectly, by the voice or by musical instruments) by means of electricity, magnetism or electro-magnetic waves, variations or impulses conveyed or guided by wires, and includes all generating, measuring, switching, signaling and other means or methods incidental to or involved in such communication.

"Wireless telephony" has the same meaning as "wire telephony", except that the waves, variations or impulses are radiated through space.

"Wire telegraphy" is the art of communicating messages by code signals (such as the Morse Code, for example) and of picture transmission, by means of electricity, magnetism or electro-magnetic waves, variations or impulses conveyed or guided by wires, and includes all generating, measuring, switching, signaling and other means or methods incidental to or involved in such communication, but does not include such devices as annunciators, elevator signals, engine room telegraphs, etc.

"Wireless telegraphy" has the same meaning as "wire telegraphy," except that the waves, variations or impulses are radiated through space.

"Picture transmission" is the art of transmitting, or receiving at another point than the point of transmission, by means of electricity, magnetism or electro-magnetic waves, variations or impulses, the aspect or shape of things, including pictures, whether still or moving, drawings, writings, forms and other graphic, printed and written matter of all kinds; and includes television.

"Programs" means pictures, news, music, speeches, sermons, advertising and entertainment, educational and similar matter, or any of them or combinations of any of them, for the purpose of exhibition, entertainment or instruction.

"Power purposes" means all prime movers and their accessories and all generation, use, measurement, control and application of electricity for light, heat, power and traction, but does not include any communication purpose.

"Public address system" means a combination of one or more telephone transmitters and one or more loud speaking telephone receivers, either adjacent to said transmitters or at a distance therefrom, operating by one-way wire telephony for the reproduction of sound with increased volume, but does not include apparatus for operation in combination or connection with or as parts of apparatus for (1) wireless telephone reception, or (2) reception of programs over electric light, electric heat, electric power or electric traction lines, or (3) the production or reproduction of sound from sound records.

"Phonographs," means all apparatus for the reproduction of sound from sound records used in or in connection with such apparatus, to be heard in the immediate vicinity of the apparatus, but does not include apparatus for the transmission to, or reception at, other points of sound reproduced from such records.

"Electric Phonograph" means a phonograph in which the sound record used therein gives rise to or controls an electric current or electromotive force in such a way that the variations of the electric current or electromotive force correspond in some way to the recorded sounds, and the electric current or electromotive force directly or indirectly brings about the production of the sound from the phonograph.

"Transoceanic" communication means all communication which crosses any ocean, gulf or sea between two continents, or between a continent and an island more than one hundred miles from its shores (islands within one hundred miles of the shores of a continent being considered parts thereof), or between two islands which are not parts of the same continent, except that communication between ships or aircraft, between ships and aircraft, or between ships or aircraft and shore, and communication between parts of the same continent, is not transoceanic communication. North America, including the Panama Canal Zone and all of Central America north thereof, is to be considered as one continent, and South America and all of Central America south of the Panama Canal Zone as another.

"The United States Government" means not only the Federal Government but also the Governments of the Philippines, Porto Rico and other federal possessions, present or future; but does not include any municipal, county or state government.

"Train dispatching" is telegraphic or telephonic conveyance of train orders or operating information between the office of a train dispatcher or similar official and railway trains or other automotive land vehicles (not including air planes or airships) or points along the line of way, for directing the movements of such automotive vehicles.

"Railway signalling" is the operation of signals, switches, brakes, stops, crossing gates, etc., controlling or signalling the movements of trains or other automotive vehicles, controlled by or in accordance with train or vehicle movements or track conditions, including block signalling, cab signals and train stops. It does not include train dispatching.

"Apparatus" includes machines, devices and appliances and the materials entering into the construction thereof.

"Household devices" are electric or electrically operated apparatus, not herein otherwise specified, designed primarily for domestic use, but do not include apparatus for communication purposes.

"Homes" means all places of residence, permanent or temporary, including, however, as to hotels, hospitals and club houses only the private living rooms thereof.

"Amateur" means one, not a professional investigator, who is more than a mere broadcast listener and who evidences his interest in the art of wireless telephony by study, investigation or experiment in the art.

"Subsidiaries" of either party are corporations a majority of whose stock having power to vote for the election of directors is owned, directly or indirectly, either by such party, or by such party and one or more of its other subsidiaries, or by one or more of its other subsidiaries. The party hereto so controlling, directly or indirectly, any subsidiary is herein called the *"parent company"* of such subsidiary.

"Companies of the Bell System" are those companies which, in connection directly or indirectly with the Telephone Company, provide a telephone service throughout the United States, or from the United States to foreign countries. These companies at present comprise the Telephone Company, Western Electric Company, Incorporated, Cuban American Telephone and Telegraph Company, and the so-called Associate Companies and Connecting Companies, and their several subsidiaries.

Any dispute arising as to the meaning or application of the foregoing definitions shall be settled by arbitration, as hereinafter provided.

ARTICLE II.

THE PATENTS INCLUDED IN THIS AGREEMENT.

The licenses provided for herein are granted and agreed to be granted under all patents, and rights to or under patents, of the United States now or hereafter during the term of this agreement owned or controlled by the parties hereto, and under all such patents hereafter issued upon inventions now or hereafter during said term so owned or controlled, and to the extent to which the parties have or may have the right to grant licenses, in so far as the inventions covered by such patents are or shall be applicable to the respective fields for which said licenses are expressed as granted or to be granted, excepting (1) as otherwise specified in connection with the several grants hereinafter contained, and (2) such patents and inventions as may hereafter be excluded from the operation of this agreement in the following manner:

A list of all United States patents under which it now holds transferable rights shall be furnished by each party to the other within sixty days from the date of this agreement. Such lists shall separately identify those patents, and shall also include those applications, as to which rights, if granted hereunder, would be restricted in scope or would involve continuing obligations not implied by law. Copies of all contracts creating such restrictions or obligations shall, upon request, be furnished by each party to the other. Thereupon, and within six months after the receipt of the lists to be furnished as aforesaid, each party may in writing advise the other as to the patents and applications described in such list, furnished by the other, which (or the patents to issue on which) it desires to exclude from this agreement; and no licenses are granted by this agreement under any patents so excluded.

Each party shall thereafter, at such periods as may be agreed upon, or whenever requested by the other party, furnish to such other party like lists of subsequent patents and applications, and upon request therefor like copies of contracts; and each party may, within six months after the receipt of any such list, advise the other in writing as to the patents and applications described in such list which (or the patents to issue on which) it desires to exclude from this agreement; and no licenses are granted by this agreement under any patents so excluded.

ARTICLE III.

SCOPE OF LICENSES.

1. All of the licenses herein granted are, unless otherwise expressed in connection with the several grants, licenses to use methods and processes, and to make, use, sell, lease or otherwise dispose of apparatus and systems in the fields in which the licenses are granted.

2. A license to make apparatus includes a license to have such apparatus manufactured for the licensee by others, subject to the provisions of this article III and article X of this agreement. No rights are granted to either party to manufacture or to have manufactured, under patents under which it receives licenses hereunder, apparatus of the character at the time manufactured by the other party, except in factories owned or operated by one or the other of the parties hereto, or by their subsidiaries, without the written consent of the party granting such licenses.

3. Every license herein granted to either party includes, unless otherwise herein provided, all incidental rights necessary to the full enjoyment and exercise of the license granted, notwithstanding that such incidental

rights may lie primarily in a field in which the other party is herein granted a license which is denominated exclusive.

4. The making, using, selling, leasing or otherwise disposing of parts is subject to the same restrictions and conditions as are applicable under this agreement to apparatus of which they are or may be parts.

ARTICLE IV.

RESERVATIONS AND EXCEPTIONS TO WHICH THE LICENSES ARE SUBJECT

1. Each party reserves, under its own patents, a non-exclusive right to make for and sell or lease to the United States Government wireless apparatus and systems for use only for other than commercial or toll purposes, and to grant to that government non-exclusive licenses to make or have made for it and to use wireless apparatus and systems, but only for other than commercial or toll purposes; and all exclusive licenses herein granted are subject to this reservation.

2. Each party reserves, under its own patents, rights in the fields and for the purposes with reference to which, and to the extent to which, it receives licenses under patents of the other party.

3. All exclusive licenses herein granted to either party are subject to licenses specifically herein granted to the other party and to rights incidental to the full enjoyment and exercise of all licenses granted to the other party, except as herein otherwise expressly provided.

4. No licenses are granted by either party with reference to the manufacture or sale of wire or cable for the transmission of electric current for light, heat, traction or other power purposes, or for telephone or telegraph purposes.

5. No licenses are granted to the Telephone Company for electric lamps or other lighting apparatus (except non-exclusive licenses with reference to telephone and telegraph signal lamps and telephone and telegraph ballast lamps for use solely in fields in which the Telephone Company is otherwise licensed under this agreement), nor for the working of tungsten. But the Tele-

phone Company is licensed to use, in the fields for which it receives licenses hereunder, tungsten purchased from the General Company, or from others having the right to make and sell tungsten, and to make, use, sell or lease (for such fields only) devices embodying such tungsten. The General Company agrees to sell and deliver such tungsten for such purposes, in wire or other practicable form to be specified by the purchaser from time to time, on the terms specified in article X hereof.

The Telephone Company agrees that, on all sales of telephone and telegraph signal lamps or telephone and telegraph ballast lamps, hereunder, to others than Companies of the Bell System, (other than lamps licensed under paragraph (*d*) of subdivision C of section 4 of article V hereof), it will pay to the General Company a royalty of 2% on the net sales price thereof.

6. The licenses herein granted to the Telephone Company, in so far as they cover rights to sell or lease carrier current, wireless or vacuum tube apparatus for use on electric railroads, are limited to sales or leases of said apparatus to the railroads; the sale of such apparatus to be installed in electric cars and electric locomotives designed or built by the General Company, as part of the original construction and equipment thereof, shall be through the General Company only.

ARTICLE V.

LICENSES GRANTED.

Subject to the foregoing reservations, each party grants and agrees to grant to the other the following licenses in the following fields of use:

1. Government Uses.

Each party grants to the other non-exclusive licenses to make for, and sell or lease to, the United States Government wireless apparatus and systems for use only for other than commercial or toll purposes.

2. Wireless Telegraphy.

(*a*) The General Company grants to the Telephone Company licenses in the field of wireless telegraphy, exclusive except as in this paragraph (*a*) provided, for combined wireless telephone and telegraph sets for use on ships; but where such combined sets are for use on ocean-going and coastwise ships of American registry (excluding harbor tug-boats and other harbor craft) the exclusive right to use, lease, sell or otherwise dispose of the same is granted by the Telephone Company to the General Company. The Telephone Company agrees upon request to make such sets and sell them for such use to the General Company upon reasonable terms.

(*b*) The General Company grants to the Telephone Company non-exclusive licenses in the field of wireless telegraphy to make and use (but not to sell, lease or otherwise dispose of, except to Companies of the Bell System) apparatus and systems for its own communication or that of Companies of the Bell System, and for use solely as an incidental facility in fields in which it is otherwise licensed under this agreement, but not for transmission of messages for the public except temporarily in emergencies due to storms or other catastrophes.

(c) The General Company grants to the Telephone Company non-exclusive licenses in the field of wireless telegraphy to make and use (but not to sell, lease or otherwise dispose of, except leases to subscribers in connection with a service given by Companies of the Bell System in t[illegible] paragraph described) apparatus and systems for the purpose of giving within the continental United States, and between the continental United States and other parts of continental North America, a business, commercial or official service limited to a particular customer or class of customers and analogous to the service given by Companies of the Bell System by wire telegraphy at the date of this agreement, commonly designated as leased wire or special contract service, but said licenses do not include the making or using of such apparatus for (1) transmission or reception for the public generally or (2) transoceanic communication or (3) transmission or reception of programs; and the licenses granted to, and the rights reserved by, the Telephone Company for the purposes covered by this paragraph (*c*) include only apparatus for the reception of such service which shall be adapted for reception only upon the wave lengths (not exceeding as to any set three specific wave lengths) upon which such service is given.

(*d*) The General Company grants to the Telephone Company non-exclusive licenses in the field of wireless telegraphy to make and use (but not to sell, lease or otherwise dispose of, except to Companies of the Bell System) apparatus and systems for television for use solely in combination with apparatus and systems for two-way telephony for the purpose of giving a public service combining television and speech, but said licenses do not include the making or using of such apparatus for transmission or reception of programs.

(*e*) The General Company grants to the Telephone Company non-exclusive licenses in the field of wireless telegraphy for combined wireless telephone and telegraph sets, other than sets for transoceanic communication, (1) for use in communication by, with and between airplanes, airships and other automotive devices other than ships and railway vehicles, and (2) for export from the continental United States for use for any purpose other than transoceanic communication.

(*f*) Subject to non-exclusive rights reserved for the purposes described in paragraphs (*b*), (*c*), (*d*) and (*e*) of this section 2, the Telephone Company grants to the General Company exclusive licenses for all purposes in the field of wireless telegraphy other than for the purposes covered by paragraph (*a*) of this section 2 and by section 8 of this article V.

(*g*) The licenses granted to the General Company in this section 2 do not cover the use of wireless telegraph stations for giving a telephone service, except as licensed in section 4 of this article V. The General Company agrees that the surplus facilities of said stations of the General Company shall, upon request of the Telephone Company, be made available to the Telephone Company or its sub-licensees, upon reasonable terms to be agreed upon by the parties, for giving a two-way telephone service; and it shall be a condition of every sub-license granted by the General Company under the licenses granted to it in this section 2 that the sub-licensee shall be under like obligation in respect of its wireless telegraph stations embodying any invention in respect of which it is granted such sub-license.

3. *Wire Telegraphy.*

(*a*) The Telephone Company grants to the General Company exclusive licenses in the field of wire telegraphy for the transmission and reception of programs over electric light, electric heat, electric power and electric traction lines, subject, however, to the provisions of paragraph (*b*) of section 5 of this article V regarding electrical interference.

(*b*) The Telephone Company grants to the General Company non-exclusive licenses in the field of wire telegraphy to make (but not to sell, lease or otherwise dispose of) apparatus and systems, and (1) to use such apparatus and systems for its own communication and for use solely as an incidental facility in fields in which it is otherwise licensed under this agreement, and (2) to use such apparatus and systems upon wire telegraph systems owned by it, or leased to it for its operation (other than transoceanic cables), for all purposes other than giving a service by wire telegraphy analogous to the service given by the Companies of the Bell System by wire telegraphy at the date of this agreement, commonly designated as leased wire or special contract service, and other than train dispatching; but no licenses are granted with reference to transoceanic wire telegraphy.

(*c*) The Telephone Company grants to the General Company non-exclusive licenses in the field of wire telegraphy for apparatus and systems for communication only in connection with the operation of apparatus for power purposes, but not for transmission of messages for the public.

(*d*) The Telephone Company grants to the General Company non-exclusive licenses in the field of wire telegraphy for apparatus and systems for communication between parts of a train (without regard to the nature of the motive power thereof), or between trains following or approaching each other upon the same system of tracks, or between trains approaching a cross-over or junction point of the systems of tracks upon which they are running, or between trains and signal towers or way-stations within short distances thereof, but in each instance only for use in connection with the operation of such trains but not for train dispatching.

(*e*) Subject to non-exclusive rights reserved for the purposes described in paragraph (*b*), (*c*) and (*d*) of this section 3, the General Company grants to the Telephone Company exclusive licenses for all purposes in the field of wire telegraphy (other than that covered by paragraph (*a*) of this section 3) on land, and over ocean cables not more than one hundred miles in length, and between the main body of the United States and Cuba; but no licenses are granted with reference to other transoceanic wire telegraphy.

4. *Wireless Telephony.*

A. IN GENERAL.

(*a*) The Telephone Company grants to the General Company non-exclusive licenses in the field of wireless telephony to make and use (but not to sell, lease or otherwise dispose of) apparatus and systems for its own communication and for use solely as an incidental facility in fields in which it is otherwise licensed under this agreement, but not for transmission of messages (as distinguished from programs) for the public except [illegible]porarily in emergencies due to storms or other catastrophes.

(*b*) The Telephone Company grants to the General Company exclusive licenses in the field of amateur wireless telephony, subject to non-exclusive rights reserved for the purposes and subject to the limitations hereinafter in this paragraph (*b*) provided; and the General Company grants to the Telephone Company non-exclusive licenses to make and sell apparatus in the field of amateur wireless telephony limited as hereinafter in this paragraph (*b*) provided. The licenses by this paragraph (*b*) granted by the Telephone Company to the General Company shall be free of royalties, but all apparatus sold by the Telephone Company under the licenses granted by this paragraph (*b*) shall be treated as if such apparatus were apparatus for one-way wireless telephone reception of programs under the provisions of paragraph (*d*) of subdivision C of this section 4 and shall be governed by all the provisions of said paragraph (*d*).

(*c*) Each party grants to the other non-exclusive licenses for headphones for all purposes in all fields covered by this agreement; provided, however, that headphones sold by the Telephone Company as part of complete apparatus for one-way wireless telephone reception of programs shall be included in the determination of the royalties payable by the Telephone Company under the provisions of paragraph (*d*) of subdivision C of this section 4.

(*d*) Each party grants to the other non-exclusive licenses in the field of wireless telephony for apparatus and systems for communication only in connection with the operation of apparatus for power purposes, but not for transmission of messages for the public.

(*e*) Each party grants to the other non-exclusive licenses in the field of wireless telephony for apparatus and systems for communication between parts of a train (without regard to the nature of the motive power thereof), or between trains following or approaching each other upon the same system of tracks, or between trains approaching a cross-over or junction point of the system of tracks upon which they are running, or between trains and signal towers or way-stations within short distances thereof, but in each instance only for use in connection with the operation of such trains but not for train dispatching.

B. TWO-WAY WIRELESS TELEPHONY.

(*a*) The General Company grants to the Telephone Company exclusive licenses in the field of two-way transoceanic wireless telephony to make and use (but not to sell, lease or otherwise dispose of) apparatus and systems for use in the continental United States; but such licenses do not include use for transmission or reception of messages offered for telephonic transmission.

(*b*) The General Company grants to the Telephone Company non-exclusive licenses in the field of two-way transoceanic wireless telephony, to make and sell to stations outside the continental United States engaged in cooperation with the Telephone Company in giving for the public a transoceanic telephone service, apparatus for use in giving such service; and subject to non-exclusive rights reserved for the purposes described in the foregoing clause of this paragraph (*b*), the Telephone Company grants to the General Company exclusive licenses in the field of two-way transoceanic wireless telephony for apparatus for export from the continental United States.

(*c*) The Telephone Company grants to the General Company non-exclusive licenses in the field of two-way wireless telephony for combined wireless telephone and telegraph sets, other than sets for transoceanic communication, (1) for use in communication by, with and between airplanes, airships and other automotive devices other than ships and railway vehicles, and (2) for export from the continental United States for use for any purpose other than transoceanic communication.

(*d*) Subject to non-exclusive rights reserved for the purposes described in paragraph (*c*) of this subdivision B, the General Company grants to the Telephone Company exclusive licenses in the field of two-way wireless telephony (other than in the field of transoceanic wireless telephony) for all purposes other than the purposes covered by subdivision A of this section 4.

(*e*) The licenses granted to the Telephone Company in this subdivision B do not include the use of wireless telephone stations for giving a telegraph service, except as licensed in section 2 of this article V. The Telephone Company agrees that the surplus facilities of said stations of the Telephone Company shall, upon request of the General Company, be made available to the General Company or its sub-licensees, upon reasonable terms to be agreed upon by the parties, for giving a wireless telegraph service, and it shall be a condition of every sub-license granted by the Telephone Company under the licenses granted to it in this subdivision B that the sub-licensee shall be under like obligation in respect of its wireless telephone stations embodying any invention in respect of which it is granted such sub-license.

C. ONE-WAY WIRELESS TELEPHONY.

(*a*) Each party grants to the other non-exclusive licenses in the field of one-way wireless telephony for apparatus and systems for the purpose of giving a business, commercial or official service limited to a particular customer or class of customers; but the licenses granted by this paragraph (*a*) do not include the making or using of such apparatus for (1) transmission or reception of messages for the public generally or to transmission or reception of programs; and the licenses granted to, and the rights reserved by, the Telephone Company for the purposes covered by this paragraph (*a*) include only apparatus for the reception of such service which shall be adapted for reception only upon the wave lengths (not exceeding as to any set three specific wave lengths) upon which such service is given and only apparatus for the transmission of such service from and within the continental United States.

(*b*) Each party grants to the other non-exclusive licenses in the field of one-way wireless telephony for apparatus and systems for use for transmitting for purposes other than that covered by paragraph (*a*) of this subdivision C, including, however, apparatus for wireless telephone reception furnished as a part of the equipment of transmitting stations; but the licenses granted by this paragraph (*b*) do not include apparatus in the field of amateur wireless telephony.

(*c*) The General Company grants to the Telephone Company non-exclusive licenses to make and use (but not to sell, lease or otherwise dispose of, except to Companies of the Bell System) apparatus for one-way wireless telephone reception (including apparatus for the reception of programs) for its own communication or that of Companies of the Bell System, and for use solely as an incidental facility in fields in which it is otherwise licensed under this agreement.

(*d*) The General Company grants to the Telephone Company non-exclusive licenses to make and sell (but not to lease or otherwise dispose of) apparatus for one-way wireless telephone reception of programs, but not for use in combination or connection with phonographs; provided, however, that the licenses granted in this paragraph (*d*) shall be subject to the following terms and conditions:

(1) Tubes (thermionic devices) sold as separate devices for use in apparatus covered by this paragraph (*d*), or in apparatus which under other provisions of this agreement shall be treated as apparatus covered by this paragraph (*d*), shall be free of royalties to the amount of $2,000,000 during each calendar year, and said tubes in excess of said amount in any year shall be subject to a royalty of fifty per cent. computed as hereinafter provided; provided that in no event shall tubes sold free of royalty exceed 1,000,000 in number during any calendar year; and provided further that where said tubes are sold as parts of receiving sets or other complete units designed for operation with such sets, such tubes shall be treated as parts of the receiving set or other unit and shall not be classified under this subparagraph (1).

(2) Receiving sets and apparatus which under other provisions of this agreement shall be treated as apparatus covered by this paragraph (*d*), or parts thereof (including loud speakers, amplifiers and tubes other than thermionic devices), shall be free of royalty to the aggregate amount of $3,000,000 in each calendar year, and such sets, apparatus or parts in excess of said amount shall be subject to a royalty of fifty per cent. computed as hereinafter provided; provided that if the sales of tubes sold as separate devices amount to less than $2,000,000 during any year, the amount of such deficiency shall be added to the amount of receiving sets, apparatus and parts which may be sold free of royalty in the same year.

(3) For any portion of the first or last calendar year of this agreement, less than an entire calendar year, during which royalties shall be payable hereunder, the amounts which may be sold free of royalty shall be that proportion of the amounts which may be sold free of royalty in the entire calendar year which said fractional part of a calendar year bears to a calendar year.

(4) The licenses granted to the Telephone Company in this paragraph (*d*) to sell apparatus for one-way wireless telephone reception of programs (and the licenses

to sell apparatus which under other provisions of this agreement shall be treated as apparatus covered by this paragraph) are licenses for sale only at retail (except as to sales for export), either directly or through the Telephone Company's own direct agents and are subject to the condition that the Telephone Company shall retain in itself, or in one or more of its subsidiaries, title to the apparatus and control of its disposition until it is so sold.

(5) The aforementioned amounts sold free of royalty, and the amounts subject to royalty, shall (except as to sales for export) be based on the actual price at which the apparatus is sold at retail.

(6) Sales for export shall be included in determining the amounts sold free of royalty, and the amounts subject to royalty, on the basis of the price at which the sale is made.

(7) In ascertaining the amount of the sales which are free from royalty and the amount of the sales upon which royalties are to be paid hereunder, where apparatus is sold any part of which embodies any invention of any of the patents included in this agreement, the selling price of the apparatus sold shall be taken as the basis; but apparatus not covered by any of the patents of the parties, when sold not assembled for operation with apparatus covered by such patents, shall not be taken into account in computing the amounts of sales which are free from royalty or the amount of sales which are subject to royalty, unless such apparatus not covered by such patents is adapted for operation with apparatus covered by such patents and is sold in such manner that its sale or its use in connection with apparatus covered by such patents would, except for the licenses granted by this agreement, constitute contributory infringement of patents of the parties under which exclusive licenses are granted to the General Company by this agreement. Where radio receiving sets are sold for use in combination with apparatus primarily designed as public address systems the sale price of the public address apparatus shall not be included in the amount of the sales which are free from royalty or the amount of the sales which are subject to royalty. Chem-

ical primary batteries, wet or dry, and chemical storage batteries, not sold as part of apparatus upon which royalties are payable hereunder, or wiring in a building in connection with a sale of such apparatus, shall not be taken into account in computing the amount of sales which are free from royalty or the amount of sales which are subject to royalty.

(*e*) Subject to non-exclusive rights reserved for the purposes covered by paragraphs (*b*), (*c*) and (*d*) of this subdivision C, the Telephone Company grants to the General Company exclusive licenses for apparatus and systems for one-way wireless telephone reception of programs.

(*f*) Subdivision A of this section 4 and paragraphs (*a*) to (*e*), inclusive, of this subdivision C are intended to make provision for all anticipated fields of use of apparatus for one-way wireless telephone reception. If it should develop that there are other fields of use of such apparatus not covered herein licenses shall be granted in such other fields of use to the respective parties in accordance with the principle underlying said other paragraphs of this subdivision C, with special reference to the interest of the General Company in the field of one-way wireless telephone reception of programs, on the one hand, and of the Telephone Company in the field of one-way wireless telephone reception for giving a service of a business, commercial or official nature, on the other hand. If the parties can not agree with respect to such licenses, their respective rights shall be determined by arbitration in accordance with the provisions of article XIII.

5. *Wire Telephony.*

(*a*) The Telephone Company grants to the General Company exclusive licenses, subject to non-exclusive rights reserved for the same purposes, and the General Company grants to the Telephone Company non-exclusive licenses, in the field of wire telephony for apparatus for carrier current telephone communication, both one-way and two-way, over electric light, electric heat, electric power and electric traction lines, or partly over such lines and partly across wireless gaps, but in each instance only for the use of the owner or operator of such line.

in the business of such owner or operator, and not for transmission of messages for the public except temporarily in emergencies due to storms or other catastrophes.

(*b*) The Telephone Company grants to the General Company exclusive licenses in the field of one-way wire telephony for apparatus for the transmission and reception of programs over electric light, electric heat, electric power and electric traction lines including the use of such lines for pick-up lines or for connecting two or more separate electric systems in connection with the transmission or reception of programs over such lines or by means of wireless telephony, but not including the use of other wires for such purposes except as licensed in paragraph (*c*) of this section 5; provided, however, that no apparatus is licensed under this paragraph (*b*), or under paragraph (*a*) of section 3 of this article V, the use of which would electrically interfere unreasonably with the Telephone Company's systems of wire communication for which it is licensed under this agreement, as the same may now exist or may hereafter normally be developed, or with the Telephone Company's exclusive field of transmitting programs by wire telephony over lines other than electric light, electric heat, electric power and electric traction lines, and the Telephone Company shall be the sole judge of the existence of such unreasonable interference. The Telephone Company agrees whenever requested by the General Company, but at the expense of the General Company consented to by it before being incurred, to co-operate with the General Company in every reasonable way to enable the General Company to develop apparatus within the licenses granted by this paragraph (*b*) which will avoid such electrical interference.

(*c*) The Telephone Company grants to the General Company non-exclusive licenses in the field of wire telephony, both one-way and two-way, to make (but not to sell, lease, or otherwise dispose of) apparatus and systems, and to use such apparatus and systems solely upon systems owned by it, for its own communication and for use solely as an incidental facility in fields in which it is otherwise licensed under this agreement, but not for transmission of messages (as distinguished from programs) for the public except temporarily in emergencies due to storms or other catastrophes. The Telephone Company agrees to furnish to the General Company, when requested, pick-up or connecting wires, if available, for its use in the transmission of programs to or from its stations for such transmission either by means of wireless telephony or over electric light, electric heat, electric power and electric traction lines, or for its use in electrical sound recording, on terms at least as favorable as the terms given to others than the General Company, and agrees that in furnishing such pick-up and connecting wires for such service there shall be no discrimination against the General Company; and, in addition to and without limitation of the licenses granted by the foregoing clauses of this paragraph (*c*), the General Company reserves non-exclusive rights in the field of wire telephony under its own patents only, for use in connection with providing for itself or obtaining from others such service or facilities if the Telephone Company shall in any case fail to furnish the same, and the non-exclusive rights so reserved may be assigned to or otherwise availed of by any other party from which the General Company shall obtain service or facilities.

(*d*) The Telephone Company grants to the General Company non-exclusive licenses in the field of wire telephony for apparatus for the distribution to an assembled audience, or to rooms within a building or a group of substantially adjacent buildings commonly owned or operated, of matter re-transmitted from apparatus for one-way wireless telephone reception, or from apparatus for reception in the field covered by paragraph (*b*) of this section 5, or from phonographs, in each case located in the immediate vicinity of such audience or within the building or group of buildings within which such distribution is made.

(*e*) The Telephone Company grants to the General Company non-exclusive licenses in the field of wire telephony, both one-way and two-way, for apparatus and systems for communication only over wires used in connection with apparatus for remote control or actuation of apparatus for power purposes and only in connection with the operation of apparatus for power purposes, but not for transmission of messages for the public.

(*f*) The Telephone Company grants to the General Company non-exclusive licenses in the field of wire telephony, both one-way and two-way, for apparatus for communication between parts of a train (without regard to the nature of the motive power thereof), or between trains following or approaching each other upon the same system of tracks, or between trains approaching a cross-over or junction point of the systems of tracks upon which they are running, or between trains and signal towers or way-stations within short distances thereof, but in each instance only for use in connection with the operation of such trains but not for train dispatching.

(*g*) Subject to non-exclusive rights reserved for the purposes covered by paragraphs (*c*), (*d*), (*e*) and (*f*) of this section 5, the General Company grants to the Telephone Company exclusive licenses in the field of wire telephony, both one-way and two-way, for all purposes other than for the purposes covered by the paragraphs (*a*) and (*b*) of this section 5; provided, however, (1) that the licenses granted by this paragraph (*g*) for apparatus for reception of programs are licenses only to make and use in connection with a service of transmitting programs by wire telephony over lines other than electric light, electric heat, electric power and electric traction lines, to lease to subscribers to such a service, and to sell only at retail (except as to sales for export) either directly or through the Telephone Company's own direct agents, and said licenses are subject to the condition that the Telephone Company shall retain in itself, or in one or more of its subsidiaries, title to the apparatus and control of its disposition until it is so sold, and (2) that all apparatus made, used, sold, leased or otherwise disposed of by the Telephone Company for distributing to an assembled audience or to rooms within a building or a group of substantially adjacent buildings commonly owned or operated, programs re-transmitted from apparatus for one-way wireless telephone reception or from apparatus in the field covered by paragraph (*b*) of this section 5, in each case located in the immediate vicinity of such audience or within the building or group of buildings within which such distribution is made, shall be treated as if such apparatus were apparatus for one-way wireless telephone reception of programs under the provisions of paragraph (*d*) of subdivision C of section 4 of this article V, and shall be governed by all the provisions of said paragraph (*d*).

6. *Power Purposes and Household Devices.*

The Telephone Company grants to the General Company exclusive licenses in the fields of (*a*) distance actuation and control by wireless, (*b*) power purposes (including apparatus for distance actuation and control of apparatus for power purposes and apparatus for indicating at remote points the condition or position, of apparatus for power purposes) and (*c*) household devices, in each case for purposes other than communication purposes; provided, however, that in so far as concerns patents for inventions relating to business of the general character which any subsidiary of the Telephone Company now conducts as jobber and any extensions of that business along similar lines (except patents covering articles of the general character which such subsidiary now purchases from the General Company, or its subsidiaries, or sells as agent for the same), the Telephone Company reserves under its own patents (but is granted no license under the patents of the General Company) the non-exclusive right for such subsidiaries to make apparatus embodying the inventions of said patents, or have them made for them, and to sell them in said jobbing business.

7. *Railroad Signalling, Radio Goniometry, X-ray Devices.*

(*a*) The General Company grants to the Telephone Company non-exclusive licenses in the field of radio goniometry for apparatus for use as part of apparatus in respect of which the Telephone Company is otherwise licensed under this agreement.

(*b*) The General Company grants to the Telephone Company non-exclusive licenses in the field of railway signalling for apparatus incidental to apparatus for train dispatching, for use only by the train dispatcher or similar official for operating at will, and not automatically, signals, switches, brakes and stops.

(*c*) Subject to non-exclusive rights reserved for the purposes covered by paragraphs (*a*) and (*b*) of this section 7, the Telephone Company grants to the General Company exclusive licenses in the fields of railroad signalling, X-ray apparatus and apparatus associated therewith, and radio goniometry.

8. *Train Dispatching.*

The General Company grants to the Telephone Company exclusive licenses in the field of train dispatching.

9. *Electric Sound Recording.*

(*a*) The General Company grants to the Telephone Company exclusive licenses for electrical apparatus for the production of sound records (which records are for the private use of the maker, and not for commercial use or sale) in combination or connection with apparatus in the field of wire telephony other than in connection with apparatus in the field covered by paragraph (*b*) of section 5 of this article V.

(*b*) The Telephone Company grants to the General Company exclusive licenses for electrical apparatus for the production of sound records (which records are for the private use of the maker, and not for commercial use or sale) in combination or connection with apparatus for one-way wireless telephone reception of programs and with apparatus in the field covered by paragraph (*b*) of section 5 of this article V.

(*c*) The Telephone Company grants to the General Company exclusive licenses for electrical apparatus for the production in homes (which records are for the private use of the maker, and not for commercial use or sale) of sound records of entertainment and educational matter, other than apparatus covered by paragraphs (*a*) and (b) of this section 9.

(*d*) Each party grants to the other non-exclusive licenses for electrical apparatus for the production of sound records other than apparatus covered by paragraphs (*a*), (*b*) and (*c*) of this section 9.

(*e*) Nothing in this section 9 contained shall be construed as granting to either party any exclusive license with respect to electrical apparatus for the production of sound records for commercial use or sale, or for the production of master records intended to be used in manufacturing sound records for commercial use or sale.

10. Electrical Phonographs.

(a) The General Company grants to the Telephone Company exclusive licenses for electrical phonographs for use in combination or connection with apparatus in the field of wire telephony other than in combination or connection with apparatus in the field covered by paragraph (*b*) of section 5 of this article V; provided, however, that the licenses granted by this paragraph (*a*) for phonographs for private use in homes for entertainment and educational purposes are licenses only to make and use in connection with a service of transmitting programs by wire telephony over lines other than electric light, electric heat, electric power and electric traction lines, to lease to subscribers to such a service, and to sell only at retail (except as to sales for export) either directly or through the Telephone Company's own direct agents, and said licenses are subject to the condition that the Telephone Company shall retain in itself, or in one or more of its subsidiaries, title to the apparatus and control of its disposition until it is so sold.

(b) The Telephone Company grants to the General Company exclusive licenses for electrical phonographs in combination or connection with apparatus for one-way wireless telephone reception, and in combination or connection with apparatus in the field covered by paragraph (*b*) of section 5 of this article V.

(*c*) The Telephone Company grants to the General Company exclusive licenses for electrical phonographs for private use in homes for all entertainment and educational purposes other than those covered by paragraphs (*a*) and (*b*) of this section 10.

(*d*) Each party grants to the other non-exclusive licenses for electrical phonographs for all purposes other than those covered by paragraphs (*a*), (*b*) and (*c*) of this section 10.

11. *Apparatus for Co-ordination of Sound and Pictures.*

(a) The rights and licenses of the parties hereto in respect of apparatus for transmitting, receiving, recording or reproducing sound in co-ordination, synchronism or timed relation with the taking, transmission or projection of pictures shall, in so far as the fields of wire and wireless telegraphy and telephony, electrical sound recording and electrical phonographs are involved, be governed by the other provisions of this agreement relating to said fields.

(b) In so far as apparatus for the taking or projection of pictures and apparatus for co-ordinating, synchronizing or timing such taking or projection in relation to the recording or reproduction of sound are not covered by the provisions of paragraph (a) of this section 11, the Telephone Company grants to the General Company exclusive licenses for such apparatus for private use in homes for entertainment and educational purposes, and each party grants to the other non-exclusive licenses for such apparatus for all other purposes.

12. *Submarine Signaling, Scientific and Therapeutic Apparatus, Shop Expedients and Other Applications.*

Each party grants to the other, non-exclusive licenses in the following fields:

Submarine signaling.

Scientific apparatus for use of laboratories, colleges and scientific societies, as distinguished from commercial use.

Wireless apparatus for use of professional investigators (as distinguished from amateurs) for experimental purpose only.

Therapeutic apparatus other than X-ray devices and appliances.

Shop tools, appliances, materials and processes, but only for the production of apparatus embodying inventions which the grantee is licensed to make and use hereunder.

All applications, not herein otherwise specified, of inventions pertaining or applicable to or to the use of vacuum tubes, and to generating (directly or from other currents), modifying, amplifying, transmitting or receiving electro-magnetic waves, variations or impulses for other than power purposes.

ARTICLE VI.

PROVISIONS WITH REFERENCE TO FOREGOING LICENSES.

1. Whenever licenses granted under the terms of this agreement are based upon rights held by the licensor under any agreement requiring the payment of royalties or other deferred payments, measured by the use made of the invention, the party accepting such licenses shall make payments measured by its use of the invention at the same rate and upon the same terms as those agreed to be made by the party originally acquiring the rights.

2. Upon the termination of this agreement under the provisions of article XIV hereof all licenses herein granted shall, during the terms of the several patents, issued or to be issued, in respect of which such licenses exist at the date of termination, continue unaffected and of the same scope and character, whether exclusive or non-exclusive, herein expressed, so far as the grantor thereof has the right to grant such licenses for such terms; and such licenses shall not be limited by the term of this agreement.

3. (*a*) The Telephone Company may grant sub-licenses under its standard form of license contract (a copy of which is now delivered to the General Company) to such operating companies (but not manufacturing companies) as are now or may from time to time be operating under such form of contract. The provisions of this paragraph (*a*) shall apply to any changed form of license contract provided that, as changed, it grants rights in the fields of the General Company no broader than those granted by the present form.

(*b*) Each party hereto may grant to its subsidiaries sub-licenses under the licenses granted to it herein; provided, however, that each subsidiary to which a sub-license shall be granted (excepting, however, sub-licensees pursuant to paragraph (*a*) of this section 3) shall either have entered into an agreement with its parent company effectively subjecting to this agreement all

United States patents then or thereafter during the term of this agreement owned or controlled by it, or have executed to the party hereto other than its parent company an instrument granting to such other party licenses under said patents co-extensive with the licenses herein granted to such other party. Use by any subsidiary of any sub-license granted under this agreement shall for all purposes of this agreement, including determination of royalties payable hereunder, be deemed to be use by its parent company, and ownership, lease or operation of any telephone or telegraph system or station by any subsidiary shall be deemed to be ownership, lease or operation of such system or station by its parent company for all purposes of this agreement.

(*c*) In addition to the sub-licensing provided for in the foregoing paragraphs (*a*) and (*b*), each party hereto may assign or grant sub-licenses under any of the rights granted to it hereunder, provided that in each instance the assent of the other party is first obtained.

(*d*) Each party may, subject to the provisions of section 4 of this article VI, sell or lease to any sub-licensee having a sub-license to use granted under the provisions of any of paragraphs (*a*), (*b*), and (*c*) of this section 3, apparatus for the use of such sub-licensee under such sub-license, notwithstanding that the party granting such sub-license may not be licensed under this agreement generally to sell, lease or otherwise dispose of such apparatus.

(*e*) All sub-licenses granted hereunder shall be subject to all limitations and obligations attaching to the apparatus or system in respect of which sub-licenses are granted, whether under the patents, or under the instruments by which any party acquired the patents or licenses under them; or under this agreement.

(*f*) No disposition by either party of rights hereunder acquired by it, shall relieve such party of any of its obligations under this agreement, or restrict the rights of the parties hereto in operating under or modifying this agreement.

4. Each party agrees that, so far as it is enabled so to do, it will, in disposing of apparatus embodying inventions pertaining or applicable to vacuum tubes, or to

generating, modifying, amplifying, transmitting or receiving electro-magnetic waves, or other apparatus or material the unrestricted sale of which would deprive the other party of rights to which it is entitled hereunder, use such precautions by contracts, leases, restricted licenses or otherwise as may be necessary or advisable in order to prevent its subsidiaries, sub-licensees, customers or others from acquiring (by acquisition of apparatus from it or otherwise) licenses to use the same which the party disposing thereof has no right to grant. In case at any time either party shall claim that apparatus made by the other and capable of use in fields in which the claimant is exclusively licensed under this agreement, has been sold in an amount exceeding the amount reasonably acquired for use in fields in which the maker is licensed under this agreement, the parties shall endeavor by agreement to determine whether there has been such excess sales of apparatus and the amount of the royalties payable thereon as hereinafter provided; and if the parties shall be unable to agree upon any of said matters, the dispute shall be settled by arbitration as hereinafter provided. The party making such claim shall, if it shall prove the fact of excess sales, not be required to prove with the definiteness which would be required in a court of law or equity, the amount of such excess sales, but the arbitrators shall estimate such amount as nearly as they can from such evidence as may be furnished by the parties and the amount so estimated shall be deemed to be the amount of such excess sales. Upon any excess apparatus so determined to have been sold the party making such excess sales shall pay to the other party royalties equal to fifty per cent. of the current retail price during the period during which such excess apparatus was sold.

5. All royalties payable under any provision of this agreement shall continue to be payable to the ends of the terms of the patents in respect of which such royalties are payable, notwithstanding any termination of this agreement.

6. The admission of validity implied in the acceptance of licenses hereunder is limited to the field for which such licenses are granted or agreed to be granted.

7. No licenses under foreign patents are now granted or are to be implied; but except as herein otherwise expressly provided the licenses to make, sell, lease or otherwise dispose of, herein granted under United States patents include the right to make, sell, lease or otherwise dispose of for use abroad in the fields for which such licenses under United States patents are granted, but not for use abroad in other fields. Each party agrees not to export to any country in which the other party has an affiliated company, apparatus purchased from such other party which such other party could not itself so export, in view of existing contract obligations, after notice of such obligations and without first securing a written waiver thereof.

8. Each party represents that in its best judgment it has no outstanding obligations which would prevent it from entering into the agreements and from granting the licenses herein expressed. If, however, it is found that there are such conflicting obligations, the present agreement is made subject to the right to fulfill those obligations.

ARTICLE VII.

INTERFERENCES.

The parties agree to use reasonable endeavors to settle, without litigation, interferences now pending or which may arise involving inventions within the scope of this agreement.

ARTICLE VIII.

ACQUISITION OF PATENT RIGHTS.

Neither party shall acquire from others rights to or under United States patents or inventions, or rights to use secret processes, applicable to the fields of the other party, of such limited character that the other party does not, by the operation of this agreement, receive licenses thereunder of the scope and within the respective fields herein set forth, unless the party proposing to acquire such rights shall first have given the other party an opportunity to be represented in the negotiations and thereby to acquire rights for its field.

ARTICLE IX.

CO-OPERATION AND EXCHANGE OF INFORMATION.

1. Each party agrees that it will, from time to time during the term of this agreement, freely permit the other to have all information in its possession which it may have a right to dispose of with reference to its standardized apparatus or methods or processes applicable to the uses of the other party in fields in which such other party is granted licenses hereunder, but any secret process so disclosed shall be maintained in secrecy by the party to whom it is disclosed. Blue prints, etc., shall be furnished at the cost of preparing the same. For the purpose of acquiring such information each party shall at all reasonable times have access (through a reasonably limited number of accredited representatives who are regular employees under obligation to assign inventions to their employers), to the laboratories, factories and wireless stations of the other, to the end that development work may be expedited and rendered the more effective.

Each party shall, with reference to inventions owned or controlled by it, under which the other party is entitled to rights hereunder and which either party deems to be of sufficient value to justify such action, endeavor to obtain or permit and aid the other to obtain proper patents thereon.

2. Each party shall afford the engineering representatives of the other the fullest possible facilities, consistent with the reasonable operation of the other, for experimenting and for developing and testing apparatus and systems for use in transoceanic telephony, and each shall at all times be given such an opportunity to make such tests, experiments and observations in the transoceanic stations of the other as do not conflict with the service then being rendered by such stations, and each party shall afford to the other such facilities for test, experimentation and observations on ships as it may be able to extend.

3. In the operation of wireless and carrier-current communication, the parties shall co-operate to the end that interference with the operations of either party, due to the operations of the other, shall be minimized, it

being recognized that the available wave lengths are limited.

ARTICLE X.

PURCHASES AS BETWEEN PARTIES.

It is recognized that each party has and will normally continue to have facilities for manufacturing certain apparatus or parts thereof which may be required by the other party under its licenses hereunder, and that a duplication of such facilities may be wasteful and uneconomical. Each party agrees that it will upon request manufacture for and sell and deliver to the other, with reasonable business promptness and within its reasonable manufacturing capacity, on receipt of orders from time to time, and at favorable prices not to exceed those charged to others (except subsidiaries and, in the case of the Telephone Company, Companies of the Bell System) purchasing in like quantities for use in the United States, such apparatus and parts as the former is engaged in manufacturing from time to time and as the latter may desire for use under the licenses granted by this agreement.

ARTICLE XI.

LITIGATION.

1. Each party shall have the exclusive right to bring suits for infringement in the fields in which its licenses are herein expressed as exclusive, joining as plaintiff in any such suit the patent owner or the party which has acquired from the patent owner the right to sue thereunder.

2. Neither party shall bring suit for infringement of patents against the other party, or against the distributors and jobbing houses owned by or affiliated with either party, because of sales by such party, or by its (or its subsidiaries') distributors or jobbing houses, of apparatus made, in the United States, by others than the parties hereto, it being agreed that the remedy in case of any such infringement shall be only by suit against the manufacturer of those devices; but nothing herein contained shall be construed as the granting of a right to sell infringing apparatus manufactured by others.

8. Each party assigns and transfers to the other all claims and causes of action which it may have against others for infringement in fields in which the licenses herein granted to such assignee are exclusive, together with the right to sue for and collect for its own use all profits and damages arising out of such infringement.

ARTICLE XII.

RELEASES.

Each party reserves to itself the right to deal with the United States Government with reference to settlement for past use of its inventions in telephone and telegraph apparatus and systems. Subject to the foregoing, each party releases the other and the vendees and users of apparatus or systems made by it, from all claims growing out of past infringement of patents, by reason of the manufacture, use and sale of such apparatus and systems by the other party, and its resale or use by such vendees and users.

ARTICLE XIII.

ARBITRATION.

In case any controversy under this agreement (except in respect of interference or priority of rights to inventions or patents) shall arise between the parties to this agreement, which they are unable to adjust between themselves, it shall be settled by arbitration pursuant to the Arbitration Law of the State of New York in the following manner:

Either party may by notice in writing served on the other, appoint one arbitrator and call upon the other to appoint a second arbitrator within thirty days after the receipt of such notice; and each party agrees that upon receiving any such notice it will so appoint an arbitrator. The two arbitrators thus appointed shall, within thirty days after the appointment of the one last appointed, jointly appoint a third arbitrator. The controversy shall be submitted to the three arbitrators in such manner as they shall direct and their decision, or the decision of a majority of them, rendered in writing, shall be final, conclusive and binding upon the parties. In the event that a second arbitrator shall not be appointed as above provided or the two arbitrators first appointed shall fail to appoint a third, application may be made by either party to the Supreme Court of the State of New York, or to a judge thereof, to designate and appoint an arbitrator or arbitrators, as the case may require, as provided by said Arbitration Law. Each party shall pay its own expenses in connection with the arbitration but the compensation and expenses of the arbitrators shall be borne in such manner as may be specified in their decision in writing.

ARTICLE XIV.

TERMINATION OF AGREEMENT.

This agreement shall continue until July 1, 1933, but shall automatically continue thereafter until cancelled on three years' written notice given after July 1, 1930, by one party to the other party.

ARTICLE XV.

FURTHER ASSURANCES.

The parties agree to execute and deliver such further instruments as may reasonably be necessary for carrying out the provisions and purposes of this agreement.

ARTICLE XVI.

SUCCESSORS.

This agreement is binding upon and shall inure to the benefit of each of the parties hereto and their several successors in business, except that either party may transfer or dispose of any part or parts of its business not involving the grant of any licenses under this agreement, and in such case this agreement shall not be binding upon or inure to the benefit of the successor to that part of the business so transferred.

IN WITNESS WHEREOF, the parties hereto have caused this instrument to be executed on the day and year first above written, by their proper officers thereunto duly authorized.

GENERAL ELECTRIC COMPANY,
By E. W. RICE, JR.
President.

[SEAL]
Attest:
J. W. ELWOOD
Assistant Secretary.

AMERICAN TELEPHONE AND TELEGRAPH COMPANY,
By H. B. THAYER
[SEAL] President.

Attest:
A. A. MARSTERS
Secretary.

II. The foregoing modifications shall be effective from and after the date of this agreement.

IN WITNESS WHEREOF, the parties hereto have caused this agreement to be executed as of the day and year first above written by their proper officers thereunto duly authorized.

GENERAL ELECTRIC COMPANY,
by OWEN D. YOUNG
Chairman of the Board.

[SEAL OF GENERAL ELECTRIC COMPANY]
Attest:
J. W. LEWIS
Assistant Secretary.

AMERICAN TELEPHONE AND TELEGRAPH COMPANY,
by D. F. HOUSTON
Vice-President.

[SEAL OF AMERICAN TELEPHONE AND
TELEGRAPH COMPANY]
Attest:
A. A. MARSTERS
Secretary.

UNITED STATES PATENT OFFICE

IRVING LANGMUIR, OF SCHENECTADY, NEW YORK, ASSIGNOR TO GENERAL ELECTRIC COMPANY, A CORPORATION OF NEW YORK.

ELECTRICAL DISCHARGE APPARATUS.

Application filed October [illegible], 1913, Serial No. [illegible]. Renewed February [illegible], 1924.

To all whom it may concern:

Be it known that I, IRVING LANGMUIR, a citizen of the United States, residing at Schenectady, county of Schenectady, State of New York, have invented certain new and useful Improvements in Electrical Discharge Apparatus, of which the following is a specification.

The present invention relates to electrical discharge apparatus operating with an electron discharge and it concerns particularly the type of device operating without gas ionization and conduction.

Such a device consists essentially of an electron-emitting cathode, and one or more anodes thoroughly freed from gas, located in an envelope evacuated to such a high degree that an electron discharge can take place from the cathode to the anode or anodes without causing appreciable gas ionization by collision with residual gas molecules.

A pure electron discharge consists of negative charges of electricity, ordinarily called "electrons", moving from a cathode to an anode in a highly evacuated space. These electrons may be emitted by a highly incandescent solid, or by certain metals illuminated by ultraviolet light, particularly the alkali metals. As each of these electrons is surrounded by a negative electrostatic field and, also when in motion, by a magnetic field, the motion of the electrons is subject to the influence of both electrostatic and electromagnetic forces. For this reason each of the electrons in a given space is influenced by the field of the other electrons in this space, an effect which will hereinafter be referred to as the "space charge". I have found that the effect of the "space charge" is to limit the current flowing with a given voltage to a value which is independent of the temperature of the cathode above a certain value. This limiting current is dependent upon the geometrical shape of the electrodes, the distance between the electrodes, and other factors. A negatively charged body located in the vicinity of the cathode will reduce the electron discharge current with a given impressed voltage and may also deflect the electrons dependent upon its position and configuration.

Some of the objects of the present invention are: to reduce the effect of the space charge in an electron discharge device; to modify or eliminate the effect of negatively charged bodies in the proximity of the cathode; to increase the discharge current with a given voltage; to furnish electrons having a relatively uniform velocity and to protect the cathode itself from mechanical injury or distortion by electrostatic forces.

With these objects in view the electron discharge apparatus is provided with a conductor located in the vicinity of the cathode and maintained at a predetermined positive potential. This conductor ordinarily assumes the form of a wire grid or grating surrounding the cathode and it is connected to a continuously maintained source of potential, preferably of low voltage.

My invention will be more fully explained in the following description taken in connection with the accompanying drawings in which Fig. 1 shows in perspective a discharge apparatus embodying my invention and suitable for converting direct current into alternating current; Figs. 2, 3 and 5 are diagrams illustrating various electrical systems of connection utilizing an electron discharge device made in accordance with my invention, and Fig. 4 illustrates a modified form of apparatus in which a positively charged plate is used instead of a grid.

In the electron discharge device shown in Fig. 1, the enclosing globe 1 has been shown as partly broken away to disclose the interior arrangement of the electrodes comprising a V-shaped filamentary cathode 2, and plate-shaped anodes 3 and 4. Surrounding the cathode is a frame 5, consisting conveniently of glass, upon which is wound fine wire constituting a grid 6 with closely adjacent turns surrounding the cathode 2. Located respectively between this grid and each of the anodes are grids 7 and 8, the function of which will be hereinafter explained.

The cathode conductor is attached to terminal supports 9 and 10 which are in turn connected to leading-in wires 11 and 12, sealed into the stem 13 of the enclosing globe in the usual manner. The cathode filament is maintained taut by being anchored by its bight by means of the spring 14 attached to the frame 5. The electrodes and grid wires consists preferably of ductile tungsten. The cathode and grids are all carried by glass stems attached to a pedestal 15. The anode stems 16 and 17 consist of tungsten or molybdenum and are held in position in the extensions 18 and 19 of the bulb by springs 20, which grip the walls of the bulb. Connection is made to the anodes in the usual manner by the leading-in wires 21 and 22. Connection to the grid surrounding the cathode is made by a leading-in wire 23. The grids 7 and 8 are preferably wound upon metallic frames 24 and 25 consisting, for example, of ferro-chrome which thus short-circuit the turns of the gird. Electrical connection is made thereto by conductors 26 and 27. The relative position of the anodes the cathode and the grids is more clearly indicated in a diagrammatic manner in Fig. 2; Fig. 1 illustrates particularly the structural features.

As shown in Figs. 2 and 3, the cathode 2 is maintained at incandescence by means of a battery 29, or other suitable externally located source of energy. The surrounding grid 6 is attached to the positive terminal of a source of potential, for example a battery 30, the negative terminal of which is connected to the cathode.

The discharge device is evacuated to the highest obtainable vacuum, the electrodes being freed from gas by operating the device while on the pump at a voltage below the value at which harmful gas ionization, as indicated by blue glow, takes place. As gas is driven out of the anode by electron bombardment, the impressed voltage is progressively increased, the removal of gas by the pump being continued. The impressed voltage thus attained before sealing-off should ordinarily be higher than the voltage at which the device is intended to operate. The degree of vacuum in the completed device while depending somewhat upon the character of the device should ordinarily be as low as a few hundred thousandths of a millimeter of mercury, preferably even lower.

The system shown in Fig. 2 is adapted particularly for the conversion of direct current into alternating current and for this purpose the anodes 3 and 4 are connected by means of conductors 31, 32 to the primary winding of a transformer 33. Energy is supplied by a direct current source of energy 34, for example, a dynamo, or a battery connected at its negative terminal by means of conductor 35 to the cathode and at its positive terminal by means of conductor 36 to an intermediate point upon the primary of the transformer 33. The grids 7 and 8 are connected by means of the conductors 37 and 38, to a source of alternating current 39 having the frequency desired for the alternating current to be produced by the device. This source has been diagrammatically indicated as a transformer altho of course any suitable alternating current source may be used. The cathode 2 is connected by means of a conductor 40 to an intermediate point on the secondary of the transformer 39.

The operation of the system above described is as follows:—When the cathode 2 is brought to incandescence it emits electrons, which travel under the influence of the impressed electromotive force to a positive electrode. When, however, a conductor, located between the cathode and an anode between which electrons are passing, is negatively electrified, the electrons are repelled in accordance with the degree of negative charge, thereby decreasing or interrupting entirely the discharge current. On the other hand, when a conductor, located between an electron-emitting cathode and an anode, is positively electrified the discharge is assisted and the current increased. Some of the electrons go to the positively charged conductor, but when this conductor has a relatively small obstructing surface, as in the case when a fine filament serves as the grid or other conducting body, very little energy will be absorbed thereby. For example, a tungsten wire having a diameter of about .0004 to .0010 of one inch wound with about 100 turns to the inch may be used but the turns per inch vary widely. When the impressed electromotive force between cathode and anode is high the amount of energy lost by the absorption of electrons by a grid having a relatively low pogitive charge is negligible.

As the grids 7 and 8 are made alternately negative and positive by the alternating source 39, the discharge current, or stream of negative charges, passes in turn to anodes 3 and 4, thereby setting up an alternating current in the primary of the transformer 33, and in that manner repeating in the divided output circuit, acting as the primary of the transformer, with amplified energy the electric waves in the divided input circuit, acting as the secondary of the transformer 39. If desired, a condenser 41 may be provided in order to absorb current variations and to neutralize the inductive effect of the transformer and provide a more rapid rise and fall of current. At any given instant either of input electrodes 7 or 8 will be negatively charged, and being in close proximity to the cathode, will tend to reduce the electron current flowing. However, when a positive field is established in the vicinity of the filament by the grid 6, this grid screens the cathode from the negative field, and assists the flow of electron current, thus making possible the combination of two repeating elements in a single electron discharge apparatus. The electrons are emitted by the cathode at variable speed but all being subject to the same static field which greatly increases the speed of all an equal amount, the differences of speed represent a relatively small fraction of the impressed resultant speed. As the positive field near the cathode opposes the current-reducing effect of the space charge, the distance between the cathode and the anodes may be increased without sacrifice of efficiency.

Some energy is lost by the absorption of the electrons by the positively charged grid 6 but as its surface is small and the positive potential may be made relatively small as compared with the voltage impressed between the cathode and the anodes, this loss will form but a relatively small proportion of the total amount of energy in the output circuit.

It is desirable that the rise of static potential of the grid becoming negative, should be rapid so as to shut off the flow of electron current completely to its corresponding anode. This result can be effected by making the alternating source 39 of high potential but this also increases the positive charge on the companion grid. A high positive grid potential increases the absorption of energy by the grid. By including a battery 75 or other source of potential in the conductor 40 connected to the cathode and an intermediate point of the secondary of the transformer 39, with its negative terminal connected to the transformer, the potential on the grid negatively charged is increased, and the potential on the grid positively charged is diminished, providing, of course, that the potential of the source 75 does not exceed the potential of the source 39. If desired resistances 77, 78, may be included in the grid circuits 37, 38, or these resistances may be replaced by a single resistance in conductor 40 to reduce current flow therein without reducing the potential. In some cases such resistances may make a separate superimposed negative potential unnecessary.

In the system illustrated by Fig. 3, an electron discharge tube is employed to rectify alternating current furnished by the primary of a transformer 42, the terminals of which are connected to the anodes 3 and 4, respectively, by conductors 43 and 44. The conductor 45 of the direct current consumption circuit is connected to the cathode 2 and the conductor 46 of the direct current circuit is connected to a point of intermediate potential upon the secondary of the transformer 42. It will be observed that the electrodes 3 and 4 will be in turn made positive and negative, current passing from the cathode to the positive electrode. Here likewise the electrode which is connected to the opposite terminal of the source, and hence is negative, would act to cut down the current passing from the cathode to the positive electrode. This effect, however, is prevented by the positively charged grid 6. In the case of a rectifier having a plurality of electrodes functioning as anodes, the current-reducing effect of the electrodes when negatively charged is especially marked as the drop of potential in the direct current load will reduce the potential of the positive electrode which is taking current. As no current is flowing to a negative electrode, it will have the full potential of the source. For this reason also the mechanical distortion of the cathode located in the unsymmetrical field would be serious were the positive grid 6 not present, whereby the cathode is screened and protected.

The positively charged body need not necessarily be grid-shaped. Fig. 4 illustrates somewhat diagrammatically a rectifying device in which a plate 47 is located between an electron-emitting cathode 48 and an anode 49. Heating current is supplied the cathode conductor by a battery 50, and a source of energy for example, a transformer 51 is connected between the cathode and the anode. Surrounding the cathode is a concave dished plate 52, which is maintained negatively charged, conveniently by connecting it to the cathode by means of a conductor 53. This ring serves to modify the static field so as to focus the electrons into a fairly well-defined stream which passes through an aperture in the plate 47 to the anode.

By maintaining the plate 47 positively charged, for example, by means of a battery 54, the passage of the electrons from the cathode to the anode is assisted. The potential of the battery 54 and hence the charge on the plate 47, may be only a fraction of the potential between supply conductors 55, 56. The electrons will be attracted to the plate 47 but will largely pass through the aperture in the same as this represents the center of static attraction. By making the potential of the plate 47 relatively low the loss of energy by the absorption of electrons on the part of the plate 47 will be relatively small, and will be more than compensated by the increase in discharge current. The rectified current may be utilized by load devices 57. If it is desired to utilize both half waves of the alternating current, two sets of the devices illustrated are used in any well-known manner, such, for example, as that disclosed in Arsem Patent #920,371, or Alexanderson Patent #998,445.

As indicated in Fig. 5 the positively charged conductor may be used to advantage in a device for amplifying or repeating weak variable currents, such as signals in radio-telegraphy, or telephony. The repeater or electron discharge tube 58 is provided with a local source of energy, for example a battery 59, which may be of very low voltage, and is connected between the cathode 60 and the anode 61. The grid 62 and the cathode 60 are connected to the secondary of a transformer 63, the primary of which is included in the antenna circuit. The latter has as usual an aerial antenna 64, and a grounded condenser 65. The grid 62 may be maintained at a definite potential by a battery 66. The cathode is surrounded by a grid 67, maintained at a perdetermined positive potential with respect to the cathode by a battery 68. When the cathode is heated by a local source of energy 69, a current will tend to flow from the cathode to the anode but this current is either prevented from flowing or is greatly reduced when the field of the grid 62 is negative. As the electrons are drawn away from the cathode 60 by the positive field furnished by the grid 67, a very low voltage may be used in the plate circuit, in fact, I prefer in some cases to use but a single cell for the battery 59, as indicated. A negative potential on the grid 62 on the other hand may be made relatively high. The current variations in the electrode circuit 72 due to the signal impulses impressed upon the grid circuit, are correspondingly great. The signals may be received by a telephone 70, or other suitable receiver, connected in shunt with a condenser 71.

The sensitiveness of this arrangement is especially marked as the electrons leave the grid 67 at substantially uniform velocity and hence are all affected to an equal extent by the variations in the negative charge of the grid 62.

What I claim as new and desire to secure by Letters Patent of the United States is:—

1. A discharge apparatus operating with an electron discharge comprising a highly evacuated envelope, an electron-emitting cathode, an anode, a conductor therein located near the cathode, means for maintaining said conductor at a substantially uniform positive potential with respect to said cathode, and separate means within said envelope for varying the electron discharge between said cathode and anode.

2. An electrical discharge apparatus comprising an electron-emitting cathode, an anode, an envelope therefor, said electrodes and the space in said envelope being freed from gas to a degree permitting a substantially pure electron-discharge to take place therein without gas ionization, a conducting body in said envelope located near the cathode, and a source of potential having its positive terminal connected to said body and its negative terminal directly to the cathode.

3. An electron discharge device comprising a highly evacuated container, a cathode adapted to be heated to incandescence independently of the operating current of the device, an anode, a conductor located in part at least between said cathode and anode, means for maintaining said conductor at a uniform positive potential with respect to the cathode, and independent means for establishing an electrostatic field to control an electron discharge between cathode and anode.

4. An electrical discharge apparatus comprising an evacuated container, an electron-emitting cathode, a cooperating anode and a conductor in part surrounding the cathode, means for maintaining said conductor at a uniform positive polarity with respect to the cathode, and means for producing a negative charge in the vicinity of said cathode.

5. The combination of an electron discharge device comprising an evacuated container, an electron-emitting cathode, an anode, a conductor coiled about said cathode but spaced apart therefrom, and a source of potential having its positive terminal connected to the said conductor and its negative terminal connected directly to the cathode.

6. The combination of an electron-discharge apparatus comprising a cathode, means for heating said cathode, cooperating anodes located on opposite sides of said cathode, a grid surrounding the cathode but spaced apart therefrom, a source of potential having its positive terminal connected to said grid, grids located respectively between said surrounding grid and the anodes, and a source of alternating potential connected to said intermediate grids.

7. The combination of a discharge device comprising an envelope, an electron-emitting cathode and an anode, a conductor located near said cathode, means for maintaining said conductor at a positive potential with respect to said cathode, a second conductor located near said cathode, and means for maintaining said second conductor at a negative potential with respect to said cathode.

8. The combination of an enclosing envelope, an incandescent cathode, a plurality of anodes, a charge-controlling conductor surrounding said cathode in part at least, a source of potential having a positive terminal connected to said conductor and a negative terminal connected to the cathode, a transformer, connections between the terminals of said transformer and said anodes, a source of unidirectional current connected between said cathode and an intermediate point on said transformer primary, charge-controlling conductors located between said cathode and said anode, and means for charging said conductors alternately negative and positive.

9. The combination of an enclosing envelope, an incandescent cathode, a plurality of anodes, a charge-controlling conductor

surrounding said cathode in part at least, a source of potential having a positive terminal connected to said conductor and a negative terminal connected to the cathode, a transformer, connections between the terminals of said transformer and said anodes, a source of unidirectional current connected between said cathode and an intermediate point on said tranformer primary, charge-controlling conductors located between said cathode and said anodes, a source of alternating current connected to said charge-controlling conductors and a source of direct current connected at the positive terminal to said cathode and at the negative terminal to a point of intermediate potential on said alternating current source.

10. The combination with an electron discharge device comprising a cathode and a pair of input electrodes enclosed in an evacuated envelope, a transformer secondary having its terminals connected to said input electrodes, a source of direct current having its positive terminal connected to said cathode and its negative terminal connected to an intermediate point in said transformer secondary, and means for impressing an alternating potential upon said transformer secondary.

11. The combination with an electron discharge device comprising a cathode provided with means for heating it to incandescence and a pair of input electrodes enclosed in an evacuated envelope of a transformer secondary having its terminals connected to said input electrodes, a source of direct current having one terminal connected to said cathode and its other terminal connected to an intermediate point in said transformer secondary, and means for impressing an alternating potential upon said transformer secondary.

12. The combination with an electron discharge device comprising a cathode provided with means for heating it to incandescence, a pair of anodes and a pair of input electrodes enclosed in an evacuated receptacle, said input electrodes being located between said cathode and said anodes, means for maintaining both of said input electrodes normally at a definite potential with respect to said cathode which is different than that of the cathode, and means for charging said input electrodes alternately negative and positive.

13. An electron-discharge device comprising an evacuated vessel containing a cathode adapted to be heated to incandescence independently of the operating current of the device, an anode, a discharge controlling electrode and a fourth electrode near said cathode, means for producing a current between said cathode and said anode, and means for maintaining said fourth electrode at a definite potential with respect to said cathode.

14. A device of the audion type comprising a thermionic cathode, an anode and an auxiliary electrode, means for supporting said auxiliary electrode, said cathode being filamentary in form, and a planary supporting frame therefor parallel to one of said electrodes and comprising spaced parallel members.

15. Parallel supporting members, and a filamentary thermionic cathode insulatingly supported at a plurality of points thereby, a grid frame at each side of said cathode, and an arbor for supporting said members and said frames.

16. A device of the audion type comprising parallel grids, a support therebetween comprising spaced parallel members, and a cathode extending between said members and supported thereby.

17. The combination in an electron discharge device of an evacuated receptacle containing an electron emitting cathode, an anode and two grids interposed between cathode and anode, means for maintaining the grid nearest the cathode at a constant positive potential with respect to the cathode, and means for varying the potential of the grid nearest the anode with respect to the cathode.

18. The combination in an electron discharge device of an evacuated receptacle containing an electron emitting cathode, an anode and two grids interposed between cathode and anode, means for maintaining the grid nearest the cathode at a positive potential with respect to the cathode, means for maintaining the grid nearest the anode at a negative potential with respect to the cathode, and means for varying the potential of the grid nearest the anode with respect to the cathode.

19. The combination of an electron discharge device comprising an electron emitting cathode, an anode, and two grids interposed between cathode and anode, means for maintaining the grid nearest the cathode at a constant positive potential with respect to the cathode, means for varying the potential of the grid nearest the anode with respect to the cathode, and means for impressing upon the anode a positive potential of greater value than that impressed upon the grid nearest the cathode.

20. The combination of an electron discharge device comprising an electron emitting cathode, an anode and two grids interposed between cathode and anode, means for maintaining one of said grids at a constant positive potential with respect to the cathode, and means for varying the potential of the other grid with respect to the cathode.

21. The combination of an electron dis-

charge device comprising an electron emitting cathode, an anode and two grids interposed between cathode and anode, means for maintaining one of said grids at a constant positive potential with respect to the cathode, means for varying the potential of the other grid with respect to the cathode, and means for impressing upon the anode a positive potential of greater value than that at which the first of said grids is maintained.

22. An evacuated vessel containing a filament electrode and a cold electrode, a second cold electrode located between the filament and the first cold electrode, and a third cold electrode located between the filament and second cold electrode.

23. An evacuated vessel containing a filament electrode and a plate electrode, a grid electrode interposed between the filament and the plate electrode, and a second grid electrode interposed between the first grid electrode and the filament.

24. An electron discharge device comprising an evacuated vessel containing an electron emitting cathode, a grid electrode surrounding said cathode and a second grid electrode outside of said first grid electrode, a stem through which leading-in conductors for at least two of said electrodes are sealed, and a support for all of said electrodes arising from said stem.

25. An electron discharge device comprising an evacuated vessel, an electron emitting cathode, a grid electrode, a second grid electrode interposed between said cathode and the first grid electrode, a stem through which leading-in conductors for a plurality of said electrodes are sealed, and a support for all of said electrodes arising from said stem.

26. An electron discharge device comprising an evacuated vessel, an electron emitting cathode, a grid electrode, a second grid electrode interposed between said cathode and the first grid electrode, and a support of insulating material within said vessel for supporting all of said electrodes.

27. An electron discharge device comprising an electron emitting cathode, an anode, a pair of grid electrodes located in different planes between said cathode and said anode, an evacuated vessel, and a support of insulating material for supporting the cathode and grid electrodes in desired spaced relation within said vessel.

28. In an electron discharge device in which a stream of electrons passes from one point to another, a plurality of grids located in different planes and successively passed by the electron stream.

29. In an electron discharge device in which a stream of electrons passes from one point to another, a plurality of grids which are successively passed by the electron stream.

30. An electron discharge device comprising an electron emitting cathode, a grid electrode, a second grid electrode interposed between said cathode and the first grid electrode, an evacuated container, and supporting means for supporting all of said electrodes from a single point in said container.

31. An electron discharge device comprising an electron emitting cathode, a grid electrode, a second grid electrode interposed between said cathode and the first grid electrode, an evacuated container and supporting means for supporting all of said electrodes from a single point in said container, said supporting means being arranged to insulate all of said electrodes from one another.

32. An electron discharge device comprising an evacuated vessel containing an electron emitting cathode, a grid electrode, a second grid electrode interposed between said cathode and the first grid electrode, a stem through which leading-in conductors for a plurality of said electrodes are sealed, and means for supporting a plurality of said electrodes from said stem.

33. An electron discharge device comprising an evacuated vessel containing an electron emitting cathode, a grid electrode, a second grid electrode interposed between said cathode and the first grid electrode, a stem through which leading-in conductors for a plurality of said electrodes are sealed, and means for supporting all of said electrodes from said stem.

In witness whereof, I have hereunto set my hand this 27th day of October 1918.

Lee de Forest Inventor
By his Attorney Samuel E. Darby

UNITED STATES PATENT OFFICE.

LEE DE FOREST, OF NEW YORK, N. Y., ASSIGNOR TO DE FOREST RADIO TELEPHONE AND TELEGRAPH COMPANY, OF NEW YORK, N. Y., A CORPORATION OF DELAWARE.

OSCILLATION-GENERATOR.

1,201,273. Specification of Letters Patent. Patented Oct. 17, 1916.

Original application filed May 13, 1915, Serial No. 27,771. Divided and this application filed December 28, 1915. Serial No. 68,967.

To all whom it may concern:

Be it known that I, LEE DE FOREST, a citizen of the United States, residing at New York city, county of Bronx, State of New York, have made a certain new and useful Invention in Oscillation-Generators, of which the following is a specification.

This invention relates to generators of oscillating, or pulsating currents and embodies subject matter divided from my application Serial No. 27,771, filed May 13, 1915.

The object of the invention is to provide a generator of oscillating, alternating or pulsating electric currents which is simple and efficient.

A further object is to provide an oscillation generator of the character referred to capable of generating oscillating, alternating or pulsating electric currents of substantially uniform amplitude.

Other objects of the invention will appear more fully hereinafter.

The invention consists substantially in the construction, combination, location and relative arrangement of parts, all as will be more fully hereinafter set forth, as shown in the accompanying drawing and finally pointed out in the appended claims.

Referring to the drawing: Figure 1 is a circuit diagram showing an arrangement of generator of continuous, oscillating, alternating or pulsating currents embodying my invention. Fig. 2 is a similar view showing a modified arrangement of oscillating generator embodying my invention as applied for use in connection with radio systems.

In carrying out my invention I employ a closed and preferably, evacuated vessel or bulb in which are located cold and hot electrodes, and I provide suitable circuit connections and current supply source to said electrodes, and where the generator is employed in connection with radio systems I associate the generator with a suitable radiating system having means connected thereto or associated therewith for altering or modifying the radiations from the system either manually, as through a telegraph key, or otherwise, as for instance, a telephone transmitter, in accordance with signal code or sound waves.

Referring to Fig. 1, U designates the evacuated vessel or bulb. Located within this vessel or bulb is a hot electrode F, which, in the form shown, is a filament and also located within the evacuated vessel U are the cold electrodes *g* and W. To the filament or glower electrode F current is supplied from any convenient source as indicated at X, which source may be a battery or a direct current generator. Where an alternating current generator is employed the frequency thereof for wireless telephone operation, should be above that of the essential frequencies of voice sounds, say for instance, fifteen hundred cycles per second, or higher. For wireless telegraph work the frequency of the generator may be very much lower, say, for example, five hundred cycles per second.

In the particular form shown but to which my invention is not to be limited or restricted, I employ two cold electrodes W in the form of plates or wings, and one cold electrode *g* in the form of a grid and I have shown the grid electrode *g* positioned between the hot electrode F and one of the cold plate or wing elements W. A circuit has one of its terminals connected to the cold grid electrode W. This connection including a source of current B to an inductance coil D. This circuit connection of electrodes *g* and W is also connected to one side or terminal of hot electrode F. The other cold plate or wing electrode W is shown connected to the other side or terminal of the hot electrode F. If desired, the circuit connection between the cold electrodes *g* and W may be suitably associated with a telephone indicated at T. This association may be accomplished through a transformer H or other suitable form of coupling.

Referring to Fig. 2, I have shown the

evacuated vessel or bulb U having two cold plate or wing electrodes A, in electrical connection with each other and two cold grid electrodes G in electrical connection with each other. The two cold plate or wing electrodes having a circuit connection to one side or terminal of the hot electrode F, which circuit connection includes an inductance coil *l*, and a source of current supply indicated at B, the positive side of which is connected to the cold plate or wing electrodes W and the negative side to one terminal of the hot electrode F. In this instance the circuit connection between the cold grid electrodes G, and the cold plate or wing electrodes W, includes a blocking condenser, indicated at C_2. Connected across this circuit is a variable capacity C_1, and included in said circuit is an inductance coil P, which constitutes, in the form shown, a coupling member in association with a coil S, in the antenna earth system N, E, the coupling being preferably a loose coupling. Where the apparatus is to be used for telephoning purposes the antenna has associated therewith or includes therein a microphone transmitter M. Where the apparatus is to be used for telegraphic communication a Morse telegraph key K is bridged across a portion of the inductance S. If desired the grid and plate circuit may be inductively associated with the plate and filament circuit through inductance L as shown. It is obvious that the current supply to the hot electrode F, or to the circuit connection of cold plate or wing electrodes W, may be controlled in any suitable or convenient manner, as for instance, by the adjustable resistance R.
